The body of the tractor swings about 10 feet above the ground, and as our illustration shows the machine has just run over the enemy's first trench. It therefore *attacks him in the rear.* In a few minutes the men from the tractor's regiment trenches will rush up and the enemy *will be under fire from two sides.* The enemy is overpowered while the tractor rolls over the second trench and repeats the operation there, and so on if other trenches are left. A less bloody variation of this may be had when the tractor stops right above the enemy's trench. By means of its steam plant live steam in great quantities may be let loose on the men in the trench below, and this method presents several advantages.

First, it is a very powerful argument to

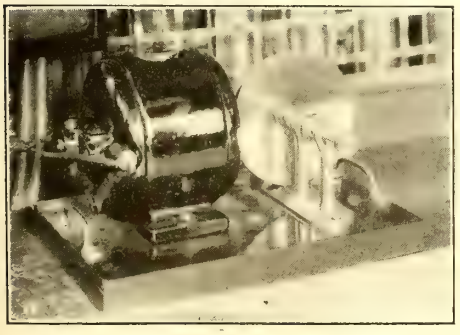
MAMMOTH ELECTRICALLY DECORATED BIRTHDAY CAKE.

What is claimed to have been the largest birthday cake ever baked is shown in the illustration herewith. It was made expressly for the 35th anniversary of a large department store in Columbus, O. It weighed nearly half a ton and required eight husky men to lift it. The dimensions were 4½ feet wide and 15 feet in circumference. It comprised nine toothsome layers, which were cut up after the celebration, so that each of the 15,000 visitors to the store received a choice morsel. The mayor of Columbus had the honor of cutting the cake.



Electrically Decorated Birthday Cake That Weighed Nearly Half a Ton.

The ring of electric candles incorporated in the design of this huge layer cake was composed of a galvanized sheet iron ring 54 inches in diameter and 3 inches wide, with a groove pressed in the center to the depth of ¾ inch. Wires were placed in the groove and secured therein with the candle top terminals projecting upward. The sockets for the candle bulbs were attached to these wires and the porcelain shields completed the make-up, with the result here observed. The lamps were lighted from a 110-volt D. C. circuit, and in finishing the cake the ring with its attached lamps was placed upon same and then the frosting and pastry decorations were covered over the whole affair, so that neither the ring nor the wiring were visible at any place.

WINDING YOUR WATCH BY MOTOR.

Does the average man stop to realize the amount of energy required to wind his watch? It would be noticeable, however, indeed if he had to wind 700 watches every day. The winding of this number of timepieces became quite an important problem in a concern testing and repairing a large number of watches.

We have all heard of how Edison wound his watch by holding the stem of it against the guide in the elevator shaft, but it is quite impossible to use this method for winding 700 watches. Therefore the machine illustrated here was devised.

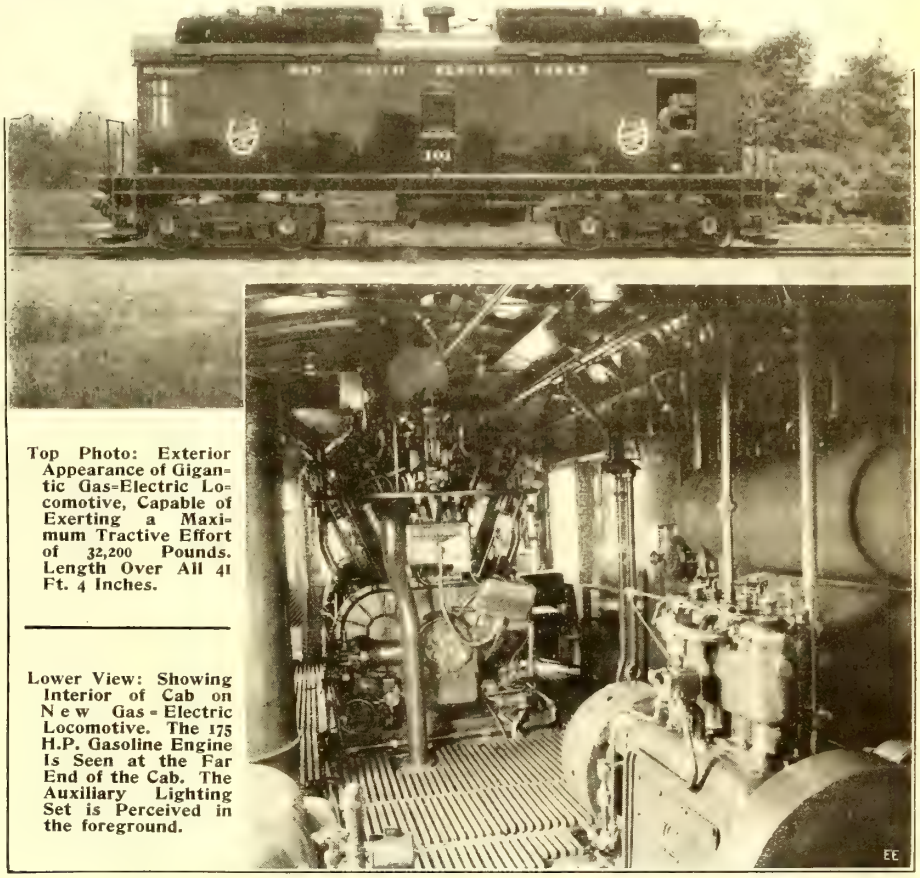
This Device Winds 700 Watches Daily.

This apparatus consists of an electric motor driving a shaft by means of a large friction pulley shown on the right. At the near end of the shaft is a small socket lined with felt which engages the stem of the watch. The only thing necessary for the watchmaker to do is to start the motor and hold the stem of the watch against the felt-lined socket.

As soon as the watch is completely wound, the tightened spring overcomes the friction between the motor shaft and the socket shaft. The spring is not wound tight enough to break it.

By this means watches can be wound very quickly and, in fact, this machine now does the work that previously required the services of several persons. Photo courtesy of New York Edison Co.

Gigantic Gas-Electric Locomotive



One of the largest electric traction corporations in the Middle West, which operates the "Dan Patch" electric lines, has recently received as an addition to its rolling stock three gigantic 60-ton gas-electric locomotives for improving its freight, passenger and terminal service.

These gigantic hybrid moguls were built by the General Electric Company. Their general external and internal appearance may be observed from the illustrations herewith. This electric traction road is said to be the first system of its kind in the world to be operated entirely by gas-electric service. One of the longest runs on this line is 107 miles.

The new 60-ton gas-electric locomotive here illustrated is of the double ended type and is built with the box type cab extending nearly the entire length of the underframe, with all the weight placed on the drivers. One engineer only is required to operate this locomotive, and it is claimed to be much more flexible in its control features and other characteristics than any other form of prime mover intended for railway purposes. The electrical generating equipment consists of a 175-horsepower, 550-r. p. m., 8-cylinder, 4-cycle gasoline engine of the "V" type. This is direct connected to a 600-volt, commutating pole, compound wound electric generator. Ignition of the engine is accomplished with low tension magnetos and the sets are started by compressed air. After starting one of these sets, of which there are two in each locomotive, the second set may be accelerated and brought up to operating speed electrically from the other set.

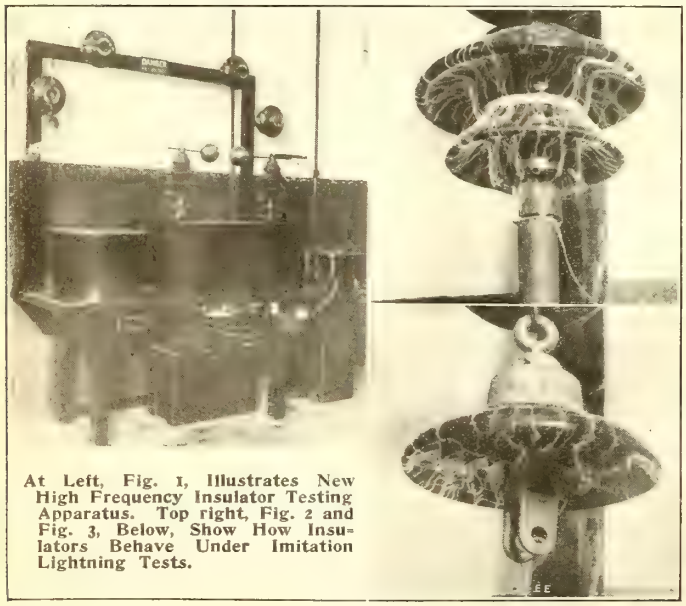
A very good feature in such designs as this, which marks a great step forward in locomotive evolution, is that the engines may rotate at normal speed irrespective of the speed of the locomotive and deliver their maximum power, which is a feature of great advantage on grades, in the case of snowstorms or other emergency conditions involving sudden, heavy current demands. There is an auxiliary gas-electric set which furnishes power for lighting the cab, headlights and train coaches.

The locomotives are propelled by means of four 100-horsepower electric motors of the commutating pole type. All four axles are therefore driving axles. The motors are ventilated by a special vacuum system in conjunction with the engines. These engines are capable of exerting a maximum tractive effort of 32,200 pounds. The length over all is 41 feet 4 inches and height over all 14 feet 10¾ inches, with an over all width of 10 feet 2 inches.

Top Photo: Exterior Appearance of Gigantic Gas-Electric Locomotive, Capable of Exerting a Maximum Tractive Effort of 32,200 Pounds. Length Over All 41 Ft. 4 Inches.

Lower View: Showing Interior of Cab on New Gas-Electric Locomotive. The 175 H.P. Gasoline Engine Is Seen at the Far End of the Cab. The Auxiliary Lighting Set is Perceived in the foreground.

The largest electric hoist in the United States has been installed in a mine in Butte, Mont. The new machine hoists at a speed of 3,000 feet per minute and can lift 14,000 pounds up a shaft 4,000 feet deep.



TESTING INSULATORS UNDER "LIGHTNING" CONDITIONS.

It has been common for many years to test insulators, particularly those intended for high voltage line work, at a potential of several times the normal working value at which the insulator is to be rated.

In the illustrations herewith Fig. 1 shows a special testing outfit as used by the Georgia Railway & Power Co., of Atlanta, Ga. These illustrations are reproduced through the courtesy of E. P. Peck, in charge of the testing department of that corporation. It has been definitely asserted that even when these insulators have been tested at four or five times the working line voltage on which they are to be operated normally that they would often and repeatedly fail for no apparent reason when the voltage piercing the insulator was known to be not more than one and one-half times the normal potential. It has been definitely deduced that the reason why the insulators fail in the manner just described is because of some high frequency disturbance on the line, as lightning, which has caused the insulators to be thus punctured. Lightning, of course, is a high frequency current invariably, and to imitate these conditions as nearly as possible has been the work of recent years of the foremost testing engineers.

The apparatus here illustrated comprises a high voltage step-up transformer, calibrated spark gap, together with oil immersed condenser, etc., arranged somewhat after the fashion of wireless transmitting sets for producing high frequency oscillations. The set here shown can be run up to 300,000 volts at 200,000 cycles. This apparatus is arranged so that the voltage may be increased by steps of a few thousand at a time and thus a considerable testing range is at the command of the engineer in charge.

Figs. 2 and 3 graphically illustrate the effect produced on the high voltage insulator as the current finally leaps over the surface when the voltage has been increased above the normal working value. Fig. 2 shows how the sparks have traversed up under and on both petticoats of the insulator; one high voltage terminal being connected to the pin supporting the insulator, while the second high tension terminal is mounted on top of the insulator. This method has been favorably received and considered by the best engineers in the country, and undoubtedly the time will shortly arrive when all transmission line insulators at least will be tested by this method, as in no other way can the effects produced by lightning be duplicated.

At Left, Fig. 1, Illustrates New High Frequency Insulator Testing Apparatus. Top right, Fig. 2 and Fig. 3, Below, Show How Insulators Behave Under Imitation Lightning Tests.

English Women Learn Wireless

The great European war has made possible the impossible and bids fair to change all the familiar landmarks and aspects with which the globe trotter is more or less familiar. For one thing, the women of Europe have taken up practically every branch of human endeavor, including the trades and professions.

At Left: Class of Enthusiastic Girl Students in the East London Wireless College. They Are Members of The Woman Signalers' Territorial Corps.

At Right: A View of the Women's Radio Class at Close Range. Here We See Them Actually Receiving Radio Messages on Commercial Type Instruments. Oh, Yes, They Understand Diagrams. Note Blackboard.

The illustrations herewith show how the English women are taught wireless telegraphy. The upper view shows the principal and a portion of the class in the East London Wireless College located at Forest Gate. These students are members of the Women Signalers' Territorial Corps. All the apparatus has been loaned by the Marconi Wireless Telegraph Co. In the lower illustration one of their multiple tuners with a magnetic detector is seen. A diagram of an oscillatory circuit is seen on the blackboard.

The young ladies are said to be very adept at picking up the wireless code and evidently mean to do their full share in the war's work whenever necessary. The women in France have taken the place of the men in practically every branch of science and industrial work. Practically all the street car motormen's and conductors' positions have been substituted by women and all the telegraph and telephone positions are said to be filled by them in a completely satisfactory manner. How these fair devotees of the radio art intend to climb aerial masts to make repairs, etc., cable reports fail to state, but we presume it is taken for granted that there will always be a man around some place to do such stunts.

NEW USES FOR VACUUM CLEANERS.

Vacuum cleaners are used to keep pool tables clean and to remove loose hair from freshly groomed horses. By grooming the horses electrically they are given a better appearance and there is no loose hair to get on the clothes.

SIGNS THAT TIMES HAVE CHANGED.

There are hundreds of families in every city that are still denying themselves the comforts and conveniences of our modern mode of living just because they have never worked out the proper answer to the question, "Can we afford it?" They have inherited the belief that electricity in the home means an expense that can be afforded only by the well to do. There are now many homes where the monthly bill for electric current in mid-winter does not exceed the cost of one roast of beef. They use the electric fan in summer, an electric heat pad in winter and electric suction sweeper each week, and the bill varies from $1.50 in June to $2.50 in December. Why not give the electric current a trial?

Miniature Electric Battleship

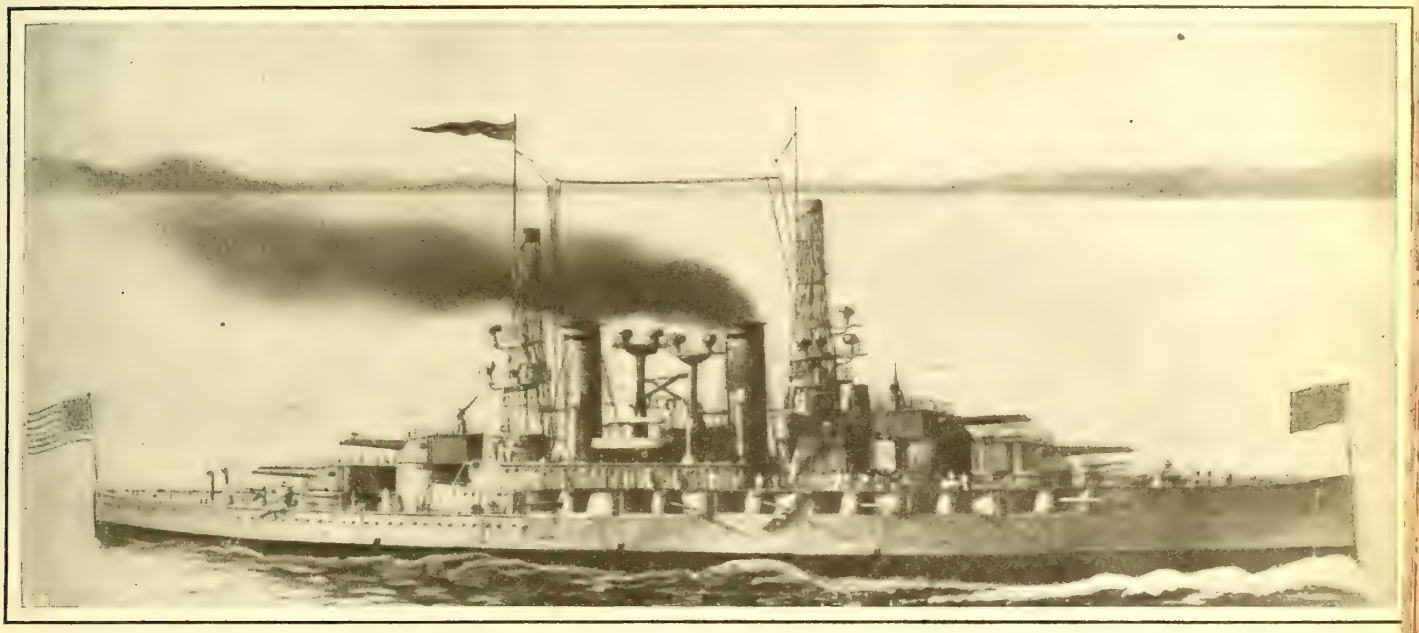
By Carrol Wakeman

A WONDERFUL electrical working model of the United States battleship Massachusetts, which took two and a half years to construct, has been recently placed on exhibition. It was built by Samuel Orkin, who labored on it an average of 16½ hours a day. This most remarkable little craft is built entirely of steel, and after setting the automatic timing device runs entirely alone. She is capable of running at a speed of 14 knots an hour for six hours, or will tow three men in a canoe at the rate of eight miles per hour. It carries 12 miniature 14-inch guns, 12 six-inch guns, four rapid-firing and two aeroplane guns, also six torpedo tubes. It is 13 feet long and two feet in breadth, having a displacement of 750 pounds and a draft of 9½ inches. She is manned by a dummy crew, which, in accordance with the size of the ship, are three inches in height. There are two derricks, which lift the miniature steam launches and swing them over the side into the water, where they run for 15 minutes entirely independent of the mother ship. The vessel is run by nine motors, three of which revolve the three propellers; the main motor developing one horsepower. The motors receive their current from specially designed storage batteries, having a capacity of 72 amperes. The portholes have lenses; but, should any water get into the hull of the ship, it would be forced out by pumps working automatically every five minutes. A rudder which has a resistance of 50 pounds steers the ship automatically in any direction.

When the automatic device is released, and the various motors commence to work, magic is out-wondered. Suddenly the clash of a miniature band playing "The Star-Spangled Banner" rings out, and as the flags are hoisted slowly signal lights begin to flash in the fighting masts, real wireless messages are being sent, miniature metal sailors run along the decks, opening the doors and shutting them, saluting exactly as though they were human. They climb the shrouded ladders and begin to operate the 12 searchlights, throwing the powerful rays in all directions, at the same time elevating them at all angles.

Then you gaze in wonder! Sharp sparks of real wireless messages are sent out, signal lights are flashing Morse code to other imaginary ships, and did you know the code you would ascertain that the officers of the dreadnought are flashing orders to other ships to fall into double battle line.

The doors in the superstructure of the ship swing open, and over 200 bluejackets, running from all parts of the deck, disappear through them into the heart of the vessel.



Suddenly an order is given, the siren whistle signals to clear the harbor, and anchors are hoisted automatically. The propellers begin to revolve and the rudder turns in response to the steering levers operated by the officer on the bridge, and this mighty engine of destruction is under way.

With her decks cleared for action and her crew below, all save the little group clustered around her commanding officer, you see her steaming away with a trail of smoke belching from her smokestacks. As she is maneuvering, the lower of the superimposed turrets swing to the right and a puff of smoke leaps from one of them.

Instantly the next gun speaks, and the next. When the turrets swing again, this time to the left and a full broadside is fired, the report is tremendous from all 12 guns.

Now the after turrets are taking up the cannonade, shooting their spirals of smoke far out and filling the air with the smell of powder. Next, the warship draws closer to the imaginary enemy, the smaller guns in the broadside batteries—the six-inch guns—come into action, swinging to a new angle at each shot.

When the supposed enemy has been sunk the battleship slows down in speed. The doors in the superstructure open again and her ship's company pour out again. The boat is steered automatically to the shore, wireless messages being sent to the victorious sailors. (The boat is steered automatically to the shore.) The band strikes up "The American Patrol," the siren shrieks, to clear her path, sailors marching, flags hoisting up. Gradually the ship draws near the shore, the band stops playing, the sailors enter the cabins and the boat becomes motionless. As the automatic devices have stopped, it would take but a minute to repeat the same or send her in another direction. Mr. Orkin intends to build next a complete fleet of boats having submarines, torpedo boats, aeroplanes, et cetera. Then a genuine sea battle in replica can be faithfully staged, giving a most wonderful sight.

A Replica of the U. S. Battleship "Massachusetts" in Miniature. It Measures 13 Feet Long and by Means of Electricity Fires Guns, Flash Searchlights, Signals by Radio, Etc., Most Realistically.

WAR EXTENDS APPLICATION OF WIRELESS.

France has about 10 wireless stations, the most powerful being the Eiffel Tower. The Germans have a great many more, especially the big station at Nauen, with the transmitting power occasionally raised up to 7,200 miles. They have a similar post in Spain, and until recently operated directly from Sayville, L. I. The latter plant is now in the hands of the United States Government, and German operators are not permitted to dispatch messages. The Sayville plant apparatus was made in Germany.

When the cables connecting America and Germany were cut the great wireless system in nowise impaired Teutonic communications directly with the United States. It has been shown that the power of the German wave from this station paralyzed almost entirely all other wireless communications. It is said that as much as 90 per cent. of the successes of the Germans offense and in escapes have been due their innumerable wireless stations.

GERMANS TAKE CABLES FOR COPPER.

Abandonment of little-used cable street car lines, so that the copper may obtained for war purposes, has been ordered by the municipality of Kiel, Germany according to a Reuter dispatch from Copenhagen, which says that the work of tearing up three streets for this purpose has begun and that about 3,000 yards of cable, weighing approximately seven tons, will thus be available.

Other lines are expected to be similarly treated in Kiel and other German cities.

The Modern Detecta-Phone

By Samuel Cohen

THE Detecta-Phone is an instrument for use whenever secret reporting of a conversation may be necessary. It is also used in aiding partially deaf people to hear. This instrument is so sensitive that the speaker may sit at a distance from the 'phone of 10 or more feet and the detective can hear the conversation accurately.

In detective work the transmitter of this apparatus may be concealed in any section of the apartment, such as in drawers of desks, in the walls, behind pictures, etc., and yet a voice in the room is accurately reproduced at the receiving end.

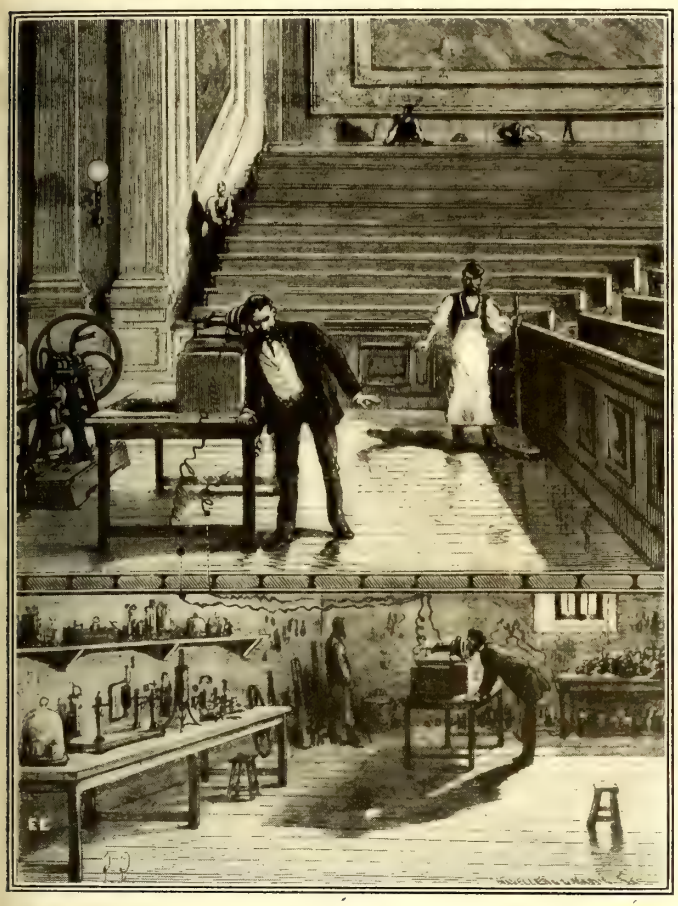
The Detecta-Phone comes under the class of electric devices commonly called "dictographs." They consist essentially of supersensitive microphonic transmitter, ade up of a large number of minute car- on balls (not grains) contained in a cup ade of the same material and a thin car- on diaphragm resting against these balls. ese parts are enclosed in a metallic case d are properly adjusted. The transmitter connected in series with a battery and ephone receiver, which latter is of the w-resistance type, and the instrument de- ibed here employs a 12-ohm receiver.

Several types of these Detecta-Phones ve been developed in the past years, but t invented by Gaillard Smith is one of most sensitive as yet produced. His in- uments are most employed by detective ncies, and, of course, a large number of them are used by deaf people. Our Fig. 1 (lower right) illustrates a Detecta-Phone used by the deaf. The transmitter is depicted on the right, while the receiver is shown toward the left. One of the features of the transmitter is a variable resistance for producing different intensities of sound in the receiver. Consequently, with this instrument one may vary the sound according to the needs of the user. The instrument is enclosed in a compact leather case, as shown, and can be carried around very readily in the pocket.

As was stated previously, the Detecta-Phone is used extensively by detective agencies. Fig. 2 (top right) portrays William J. Burns, the famous detective, using one of Mr. Smith's instruments. The transmitter is held in his left hand, while the index finger of his right points toward it. Note that double headset 'phones are used by detectives in order to get the full value of sounds produced in the transmitter. Practically every investigation made by the present detectives is entirely done by the use of these supersensitive telephonic instruments.

This inventor has also turned his mind to the development of these instruments for office work. Fig. 3 (top left) illustrates this application. Mr. Smith himself is seen using his Voca-Phone, which merely consists of a transmitter T of the type that has been previously described and two loud-speaking telephone receivers R R enclosed in a wooden case with suitable horns provided on each receiver, as is clearly shown in our photograph. One of the most important features of this Voca-Phone lies in the method of calling a certain party on the line. This is done by moving the transmitter signal arm toward the point on the scale corresponding to the party wanted. A small indicator is connected to this transmitter arm and travels across a small scale showing where this particular point is located. This scale is shown at the bottom of the Voca-Phone. A small push-button is provided on top of the instrument and it is used for calling purposes. In using this instrument one need not stand near the transmitter as in the present mode of telephoning, but the user may sit comfortably back in his chair and simply talk in a moderate tone. His voice is very readily transmitted to the receiving party.

op Left: Mr. Gaillard Smith, Inventor of Detecta-Phone, Using His Loud Talking Desk Telephone. Top Right: Detective Wm. J. Burns Uses the Detecta-phone. Insert View Shows Parts of New Tuned Microphone. Lower Left: Craig Kennedy, of Movie Fame, Employs the Smith Voca-Phone. Lower Right: New Supersensitive 'Phone for the Deaf.



The Voca-Phone has been utilized recently in "The Exploits of Elaine" film. Fig. 4 (lower left) shows "Craig Kennedy," the detective, receiving some startling information with it.

One of the latest achievements in this line is a new "transmitter" whereby the musical "keys" can be exactly reproduced, and Fig. 5 (top right) shows this transmitter dissected. The upper central portion of the picture shows the make-up of the interior of the transmitter. A is the transmitter shell, made of a very light composition metal, and B the carbon cup. This cup is made of a special grade carbon, chemically treated, and contains six small holes as perceived. These cavities contain a large number of highly polished carbon balls, which are imported from France. These balls are hollow, making them exceedingly light for their size. The most important feature of this transmitter is the very small resistance coil C. A small contact arm D is used to vary the resistance on this coil. In order to produce a particular musical "key" the small handle D is moved to a certain point on the scale which is provided in the shell. The cap of this transmitter is shown on the right of the photograph, while toward the left the receiver is shown. When the diaphragm and cap are threaded upon the transmitter and properly adjusted it is a complete unit of itself, and can be carried around quite easily without distorting the interior parts.

When Bell Introduced the Telephone

1916 Is the 40th Anniversary of the Telephone

The telephone has become such a matter-of-fact apparatus that to-day none of us hardly ever stop to realize that it is possible that less than 40 years ago the telephone was purely a laboratory device of few and doubtful virtues. Men there were, and highly educated ones at that, who scoffed at Alexander Graham Bell's "musical ear," as it was at one time called, but so it has been in all ages with new discoveries.

Early Demonstration of the Telephone by Bell.

Bell, however, was a persistent and indefatigable worker and, unlike some inventors who have not lived to see the "child of their brain" developed and perfected to the wonderful degree attained by the telephone, he and his early assistant, Mr. Watson, have lived to see the telephone on practically every man's desk and on the wall of nearly every dwelling in this country and abroad.

The interesting illustration here reproduced is from an old wood cut and shows Prof. Bell trying out his somewhat heroic size telephone of early vintage in a lecture hall at Boston prior to a lecture and demonstration of the speaking telephone. Even the man with the brush is apparently somewhat startled, as well he might have been, for the telephone in those days was considered by most people as either a pure fake or as an incredible scientific monstrosity, but Bell knew better. In most of his early demonstrations and lectures it was usual to run a short copper wire line or circuit to Bell's laboratory, the illustration showing such an arrangement. In this case Mr. Watson did the talking at the labratory and the speech was reproduced by one of Bell's "speaking ears," which part of the human anatomy it very much resembled in those days, to be sure.

It must be realized that the apparatus with which this early inventor was struggling was a very crude and much misunderstood quantity. Nothing definite was known about the proper diaphragm to use, nor its size, nor was there anything definite known about the proper strength of the magnets to use, nor with what size wire they should be wound. Even though the proper size wire had been known, it is doubtful if it could have been procured, as magnet wire in those days was very scarce and usually had to be made to order at great expense.

Mr. Watson, who recently lectured before the New York Telephone Society on some of his early telephone lecture experiences in conjunction with Prof. Bell, related some amusing circumstances surrounding the public demonstrations in which the telephone did everything but talk. In some cases, needless to say, it took but very little to thoroughly provoke and send home an audience who were expecting to hear a *loud and perfect telephone*, "right off the bat," so to speak.

However, Bell's little instrument lived up to its promise in most instances and proved beyond the shadow of a doubt that the inventor could really reproduce the human voice by electrical and mechanical means. Mr. Watson mentioned one occurrence which had New Brunswick, N. J., for its locale. On this particular glorious occasion there was to be no less a personage than a grand opera soloist from New York City, who was to sing into the transmitter of the telephone at some distance from the lecture hall and the audience was thus to have a musical as well as a scientific treat, it was promised. But, like a great many other such things on which we calculate to the final dot, things did not go right, for the reason that the opera singer's voice was not quite suited to the telephone, of that day at least, so Brother Watson had to fill up the rest of the evening with suitable selections from his not too extended repertoire, and the audience went home well pleased, and none the wiser.

THE MYSTERY.

By G. LaPalma.

I AM the Swift—I am the Beautiful—I am the Terrible—I envelop the world with My Strength, and men thank God that I am, yet tremble in fear of My Approach.

I am old—so old the mind of man cannot conceive numbers sufficient to count the years of My Being, but still I am the Personification of Youth and Power.

For ages and ages I have played through the Heavens, and deep in the Bowels of the Earth I have wrought Mysteries yet unknown to man. I have lit up the skies with My Presence, and at the deep roaring boom of the thunder I have wrapped whole Forests in Sheets of Fire, smitten rocks to fragments, and sent, in panic, the wild beasts rushing through the jungle. I have played 'round the spindling towers man built, leaped o'er mountains, moved the wild sea, and found My rest in the bodies of people who know not My Presence.

Now man has found Me—A willing servant, I fetch and carry, lighting man's home and the streets, speeding his words on currents of air to far-distant countries, turning the wheels of thousands of mills, driving his cars in the city and doing his toil in the country. Oh! Countless are the things I give in Light, in Heat, in Power, yet even the ones who know Me best know nothing about Me. And though their hands are bold, their hearts are timid.

I am the World's Mystery. I am the Terrible, the Beautiful, the Omnipotent.

I am ELECTRICITY!

ALESSANDRO VOLTA.

Alessandro Volta, the inventor of the electric battery, was born in Como, Italy, Feb. 18, 1745, in a house where the Volta family had lived for more than 300 years. When a child, strange as it may seem, he was very backward. He was four years old before he spoke even his first word "No." From the time of this event, however, his mind seemed to turn entirely to the wonders of nature.. At 17 he won prizes in philosophy. When he was 18, the famous Abbe Nolet, impressed with the boy's great knowledge, had him write essays on electricity for the great men of the day, for people in general knew very little about this mysterious force at that time.

His first formal papers were issued in his 24th year. Fourteen years later appeared the Volta *electrophorus,* followed by his *electroscope*. Shortly afterwards Volta was made professor of physics at Como, and the year succeeding accepted what became a 40 years' professorship at Pavia. Experiments here led to the discovery of the *Voltaic pile* or battery, the first device ever made for producing continuous electric currents.

Famous throughout Europe, Volta received many honors, being created a Senator and a member of the French Institute. He remained personally, however, exceedingly unpretentious and was much beloved by the Italian peasants, who called him. "Il mago benefico," meaning beneficent magician. He died in 1826, but his name will live as long as electricity stands as our motive power, because the unit of electrical pressure has been designated as the Volt.

Alessandro Volta, After Whom the Volt Is Named.

The Electric Gyro-Cruiser

A Rolling Electric Gyroscope Fort of the Near Future. By Eric R. Lyon, A. B.

THE world will have wars for generations yet to come, but the time is near at hand when their destruction of human life must cease. How is this to be? Simply that all future war must be naval warfare, by which we mean there must be a navy for each of the three elements, earth, air and sea. We have our navy on the sea, and we have begun our navy of the air. Who knows but that our last and greatest navy stands now upon the threshold of human ideas, awaiting only a proper invitation for its entrance into our affairs?

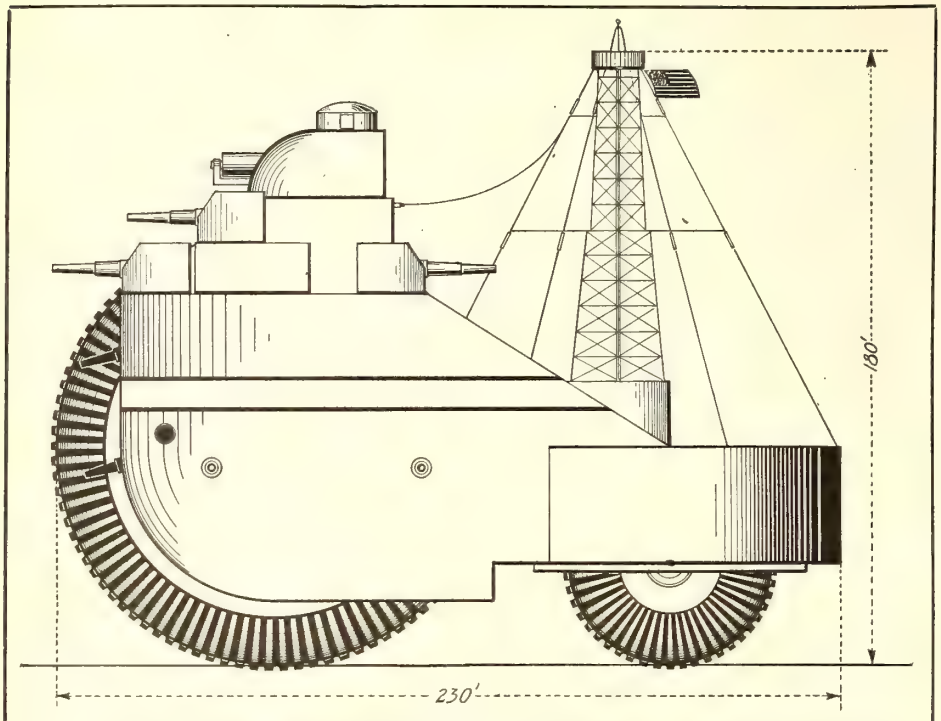


Fig. 1. Side View of Possible Land Cruiser of the Near Future. It Could Smash Any Fort With Its 42-Cm. Guns.

Suppose Great Britain's giant navy could now come up out of the sea into the plains of northern France and, mounting itself upon wheels, dash in single line formation at express train speed upon one single, unsuspecting and strategic point of Germany's hundreds of miles of battle front. What would happen?

We are told that "this is a war of ammunition;" that the decision of this war is practically a question as to which side can ultimately hurl the most tons of shot and shell into the trenches of his opponents. Now we know that if you and I and Smith and Jones and all of our neighbors are strung out over a hundred miles of battle front it is going to take an enormous amount of shelling to shell us out. But if the enemy should suddenly concentrate all of his fire upon Jones' pasture, or even upon 15 miles of battle front adjoining the pasture, there is not going to be one man left alive in all of that harnel ground to prevent the enemy breaking through. This, in brief, is the tactics of the present war. The enemy does break through. His infantry runs, his cavalry gallops and his big guns creep; all trying to get through the gap in our lines. In the meantime the warning has gone out broadcast to all of us. We rush in our reserves, and move up our own big guns to defend the breach. We storm the field. We mow down his necessarily massed ranks as with a reaping machine. We convert that 15 mile breach into a veritable inferno of hail, wind and destruction; or steel, fire and blood. The enemy is forced to retire; that is, all of him left to retire. We close up the breach, dig in again and await the next assault. This also is the tactics of the present war. Our infantry can move as rapidly as the enemy's infantry; our cavalry can gallop as hard as his cavalry, and our big guns can creep as slowly as his big guns. Consequently we were there in force before he could break through far enough to do him good. The net result of the whole encounter is another blood sacrifice to the war demon, and another call for ammunition on both sides.

Transferring ourselves from Jones' pasture to a point overlooking that select portion of the German battle front which we before mentioned, we may now imagine what begins to happen as the great British fleet comes in range behind the distant horizon. Our first warning of the impending battle is the increasing rattle of machine guns in the clouds, as the few local scouts of the German aerial fleet flee before the concentrated and overwhelming British aerial navy. Presently down comes a German Taube in flames. The British planes are circling far overhead and are signaling the ranges to the British gunners behind the horizon. The staccato roar of the German anti-aircraft guns has begun There is a distant rumble. The one remaining door of the hut in which we have taken refuge shudders, and immediately 10 or 20 bursts of flame search out the German batteries. In range of this 15 or 20 mile strip the Germans have 11 big howitzers. These are the chief concern of the British gunners. The British aerial fleet signals back the results. In the meantime one Taube scout has succeeded in landing behind the German lines. Ranges and movement of the British land fleet are immediately 'phoned to the German gunners. The big howitzers open fire, but the British aerial fleet, pursuing the Taube scout, had signaled warning to their land fleet when they could not prevent the scout's landing; and so, when the German 42-centimeter shells tear up a certain plot of ground behind the horizon it is from another point behind that ominous line that the first great answering salvo thunders forth. Through the glass we observe a distant German battery go up in flame and twisted steel. The thunderings become incessant and they seem to be coming nearer. Their salvos must be finding the targets. Suddenly the field has become alive with the bursts of six-inch shells seeking out the Germans' lesser batteries. Panic reigns. Through our glass we can see men and cannons dashing madly to new positions away from the bursts of those deadly pursuing shells. Yet not a man can we see going to the rear. The Germans have even in their despair resolved to stand their ground and die before the overwhelming onslaught. But neither do the British shells fall among the massed German infantry reserves, nor in the trenches armed only with machine guns and men helpless in the vortex of

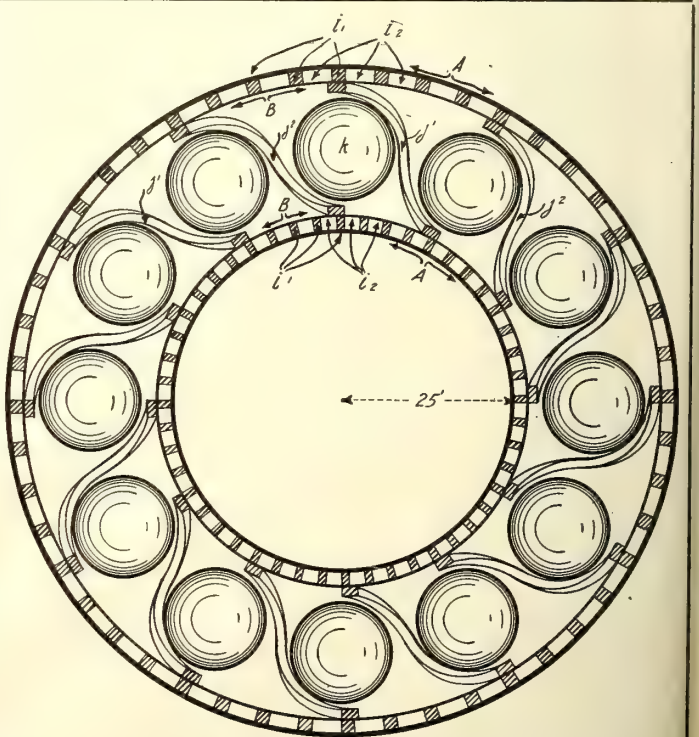

Fig. 3. Sectional View of Massive 2,000-Ton Liquid Gyroscope for Maintaining Equilibrium of Land Cruiser.

this maelstrom, for Britain has not elected to slaughter her enemies, but to overcome and to disarm them.

At last the hail of shell has ceased in the district under our observation and has swept out like a scythe into the far outlying districts. The breach has been made. The British monsters appear upon the horizon thundering, flaming, racing; bearing down upon us at express train speed. Onward they come. Presently one sweeps past into the gap and then another and another.

The memorable raid of the British land fleet had begun. It is recorded—and so it will be when the imagined incident here pictured shall have become a matter of past history—it is recorded that the British land fleet, having broken through the German lines, cut a swath of destruction through to Berlin more effective than even the famous Sherman's march through Georgia, and as they rode they destroyed every means of communication, of transportation; every munitions depot and provision depot; and ending with the destruction of the great Krupp works, there followed the surrender within a few weeks of the whole German army for lack of provisions and munitions. A new epoch was begun.

This is the picture of the possibilities of the new arm of military power. Now let us consider the probable form of its machinery. The form which first suggests itself is, most naturally, an overgrown reproduction of the common four-wheeled truck or wagon, and if such a device were designed to operate only over level ground or over especially prepared roads of about 100 feet in breadth it would be capable of good service and great speed. It would be possible to construct such roads all along the coastal country to be defended, and yet the four-wheeled units would be sadly hampered by their inability to operate away from the ideal conditions so prepared. If a unit of the future land navy, or a land cruiser we may call it, is to be of real service it must be able to maneuver anywhere over any kind of ground except precipices, and it must be able to make express train speed over common country roads and over the fields of gently rolling country. A device of this type is possible only when it shall employ some other means than a broad wheel base to maintain itself upright. Indeed, if the land cruiser is to be operated over country roads the breadth of its wheel base cannot exceed the breadth of the road, some 25 or 50 feet, which fact would necessitate balancing the structure upon not more than two great wheels—bicycle fashion. Going at full speed our huge device would be able to balance itself after the manner of a bicyclist, but it must also be able to maintain itself firm and upright even when standing still. To accomplish this there is one practical means of which we are aware, and that is the gyroscope.

Let us then call our land cruiser a gyro-cruiser. A likeness of what this may be we have in Fig. 1. Gyro-cruisers will begin, of course, very humbly, and at first will be gyro-trucks rather than gyro-cruisers. The conditions of mounting the gyroscope in the gyro-truck; the conditions of mounting the weight of the structure upon its wheels and, in fact, almost all of the conditions governing the small device will be different from those which will be found for the huge machine. So it is not with the steps upon the way, but with the type of the full-grown cruiser, of the gyro-navy in its prime, with which we are now concerned. Such, we may imagine, is the American gyro-cruiser shown in Fig. 1, with its extreme height of 180 feet from ground to top of fire control mast, its extreme length of 230 feet, its maximum breadth or beam of 87 feet and its maximum wheel breadth of 25 feet. The weight will be about 20,000 tons, one-tenth of which, 2,000 tons, will be the weight of the liquid gyroscope carried in the rim of the great wheel. The latter may be seen projecting downward and forward of the main substructure in the diagram, Fig. 1. The gyro-cruiser will mount 12 17-inch guns (or will they by that time have grown to 27 inches?) in six turrets, three of which are shown, the other three being similarly placed on the other side of the superstructure, and will be able to fire a salvo of eight guns in nearly every direction from the cruiser. Instead of the customary arrangement of low caliber guns, as in a battleship, an arrangement which is made necessary by the manner of firing with respect to the roll of the ship, the gyro-cruiser will mount in the 40-foot crown turret shown a huge machine gun, comprised of a rotating cylinder having mounted in it a sufficient number of complete and individually recoiling six-inch rifles, which shall be electrically fired as they successively pass through a predetermined firing position. One man will be able to aim and control the fire of a torrent of six-inch shells, and thus a weapon will be provided which, being peculiarly adapted to the gyro-cruiser, will give the latter added superiority to any other type of military unit operating upon the land. The great wheel shown in Fig. 1 is the traction wheel, and it is 108 feet in diameter from one beveled, cutting-edge foot to the other. The "little" wheel, which is 60 feet in diameter, is the steering wheel, and is also the balancing wheel—a fact which is apparent when we consider that in order for a gyroscope rotating in a vertical plane to exert its balancing power about a horizontal axis, it must be able to swing freely about a vertical axis. The uses of the aerial and fire control mast are obvious.

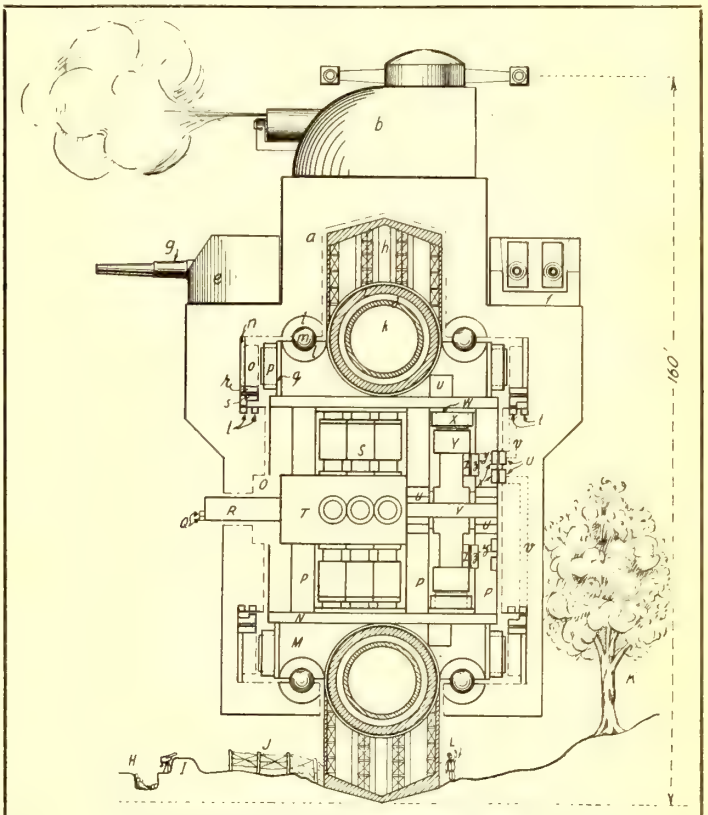

Fig. 2. Front Sectional View of Mastodonic Land Cruiser of the Future. Note Comparative Size of Man Here Shown.

Passing to Fig. 2 we have a detail, vertical cross section cutting the cruiser in a plane passing up through the center of the great wheel. We will follow the latter in explaining this diagram. On top is the crown bridge. It is heavily armored, rotates like a turret and carries the armored range finding arms, the eyes of which are now staring at the reader. Other range finding stations will be located at the top of the first control mast and at various points about the cruiser. It shall be the duty of these stations, not only to obtain the ranges of the enemy's positions, but to maintain an accurate running survey, analogous to the log at sea, from which the exact position and orientation of the cruiser may be told at any time. The complete control of the cruiser will be centered in the crown bridge, but there will be duplicate control stations in the main bridge (a) and at other points. The officer on watch at the crown bridge's range finder will have complete control of the cruiser, and he will electrically train and fire all of the guns, at the same time following the results of his own operations through the huge telescopic range finder.

(b) is the crown turret carrying the six-inch rifle machine gun described; (a) is the main bridge, offices, range plotting rooms, etc. Forward of this, but not shown in any of the diagrams, is the main searchlight station; (e) is a 17-inch gun turret, side view; (f) is the same, but looking into the business end of the guns; (g) is a 17-inch gun; (h) is the bevel-faced and very heavily armored foot or rim of the great wheel.

All inside of the broken line .—.—.—. is part of the great wheel and rotates with it. The armor of (h) is put on in plates parallel to the plane of the wheel, which is to say, perpendicular to the plane of the section. The plates will be welded together, making the rim of the great wheel one solid mass of steel capable of supporting the weight which it must bear and capable of withstanding the enormous centrifugal or bursting effort of the liquid gyroscope—the latter is carried immediately below (h) in (i), (j) and (k).

(i) is a cross section of the lining of alternate magnet coils and iron rings in the tube of the liquid gyroscope; (j) is the space in which is wound the spiral of *non-magnetic* steel which causes the liquid to spiral round the tube in a second rotation impressed upon the primary one; (k) is the hollow propelling ball of iron and steel faced construction, 15 feet in diameter, which floats in the liquid and which is sucked around and around the tube by a rotating magnetic field, just as is the action upon the shell in the proposed electro-magnetic gun: (1) is the section of a ring of heavy welded armor which, like the ar-

New Telephonic Novelties

LOUD SPEAKING TELEPHONE A BOON TO SALESMEN.

With this new adaptation of the loud speaking telephone, show window demonstrative advertising becomes a really convincing argument. It is no longer necessary to ask the audience to stand out in front of the window and read placards; instead, the demonstrator telephones his information right into the crowd, and he can tell them in the most business pulling arguments just why they should buy his wares.

Photo by Paul Thompson

This Salesman Talks to His Public Through a Loud-Speaking Telephone Fastened Outside the Show Window.

This new telephone apparatus for show window demonstrator's use was perfected into this highly practical instrument by B. H. Hogan, who, being a salesman, realized how important it is in selling goods to talk personally to the prospective customers.

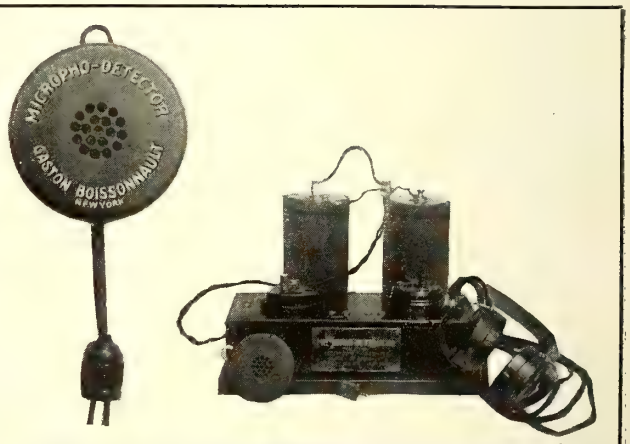
The apparatus is a simple affair which can be detached in a few minutes and packed in a medium size traveling bag. It consists of a transmitter, into which the demonstrator speaks, just like into an ordinary telephone, but at the other end of the line is a horn, similar to that on a phonograph. In this horn, which is clamped to the building, just outside of the demonstrator's show window, is a strong electromagnetic reproducer which takes up the sound waves and throws them up against a sound board in the rear end of the horn. They are deflected back and out of the horn into the listening crowd. So strong is the voice reproduced that it can be plainly heard amid the surrounding street noises for a distance of 25 feet from the window. Sometimes two horns are employed, located 10 to 30 feet apart, to accommodate a large crowd, so that all may hear clearly every word the demonstrator says.

This new telephone derives its electrical current either from an electric light socket of 110 volts, or, in case no current is at hand, from batteries producing 18 volts. It will work either on direct or alternating currents; but, in case of the latter, the voice is harsh but by no means so indistinct that every word cannot be understood.

The apparatus pictured is being used by the inventor, it being the first one to be put to practical use in this line. The novelty of the situation never fails to draw a large crowd.

LATEST ELECTRICAL AID TO THE DETECTIVE.

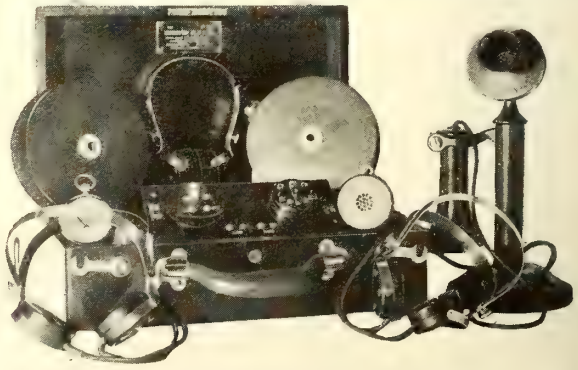
One of the greatest obstacles encountered in the present dictagraphs, as used by detectives, is that of the unnecessary noises produced by the super-sensitive transmitter due to vibration, etc. Although various devices have been developed for the purpose of eliminating these sounds or side-tones, none of them has proved much of a success, but the one invented by Gaston Boissonnault, a prominent worker in this field, has shown far more superiority in its acoustic qualities than any one of the dictagraph type of instruments heretofore produced.



His transmitter or "sound collector," as the inventor calls it, is clearly shown in Fig. 1. This is constructed in the same way as in the standard type, but the various parts are more finely built and the carbon balls and carbon diaphragm are very highly polished. The outside side-tone noises are eliminated by the proper adjustment of the transmitter.

The receivers are a very important factor in this instrument; they are of the low resistance type, some of them varying in resistance, depending upon the condition under which the instrument is used; that is, some instruments require a low resistance 'phone because of the acoustic qualities of the room where the transmitter is placed; if it is a large room, a very low ohmage 'phone will be required.

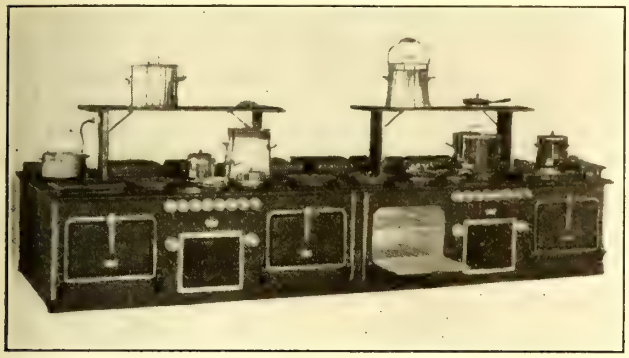
The inventor, Gaston Boissonnault, has succeeded in improving his apparatus to such a degree of perfection that he has developed an instrument for detective work, and many of these are at present employed for that purpose. One of these detective type instruments is illustrated in Fig. 2. One of the clever features embodied in this outfit is the "fake" desk telephone seen at the right of the case. This looks exactly the same as the standard desk style instrument, but instead of having a regular transmitter a sensitive microphone of the type above described is placed in the microphone shell. The receiver is a "dummy" and it is not connected to any part of the telephone. Only two wires are brought down from the transmitter. This "phoney" instrument excites no suspicion whatever, as it appears to be connected with the usual Central Exchange and is naturally out of use as the receiver is on the hook, apparently. The listener can, however, hear through the instrument whether the receiver is on or off the hook. Three sets of receivers are used with the apparatus; one being seen on either side of the case and one in the center of the cover in the picture. The instrument is installed with a sound regulating switch. Two reels, carrying flexible cord, are shown standing against either end of the cover. The batteries are enclosed in the case, thereby making the complete outfit thoroughly portable and ready for instant service.



Another instrument of similar character is depicted in Fig. 3. This is of a smaller size and intended to be used in factories where several of these transmitters are located in different departments, while the receiver is placed either in the president's or manager's office, and in this way the "boss" is always secretly informed as to the condition of affairs in any particular department. He is also informed, secretly of course, as to whether his employes are talking for or against him, and thereby he can prevent strikes, providing the employes are plotting same, and in this way he is constantly informed about the inside conditions in his entire plant.

Several of these instruments have been advantageously used by several of the warring countries in detecting spies; plots were thus frustrated that were being talked over in the buildings and mansions around the battlefield.

At the Left (Fig. 1): New Dictagraph Microphone; at the Right (Fig. 3): Small Model of Dictagraph Set for Detective's Use.



Below (Fig. 2): Complete Dictagraph Outfit for Detective's Use. Dummy Desk 'Phone at Right Contains Microphone.

Only 3.2 per cent. of fires requiring the attention of New York's fire department during 1914 were charged to electric origin.

Monster Electric Range to Cook for 1,500 People

Following a recent investigation of the practicability of electric cooking, the Montana State Hospital for the Insane, at Warren Springs, Mont., has purchased one of the largest electric ranges in the world for immediate installation in connection with an unusually efficient system of food handling and serving between the hospital kitchen and the dining rooms. The range is the largest ever built and has a total connected load of 69 kw. It is built in four similar sections, each 7½ ft. long and 2 ft. 9 in. wide, and is to be installed with sections back to back, occupying a floor space 5½ by 15 ft., enabling the cooking staff to work on both sides.

Giant Electric Range to Cook for 1,500 People at Montana State Hospital.

In general design the range is similar to one installed by the same manufacturers at the Southern Indiana Hospital for the Insane, which provides for 1,000 persons, but the Montana range has eight ovens instead of six and a proportionate increase in the top equipment. There are two ovens in each of the four sections, each oven having sufficient capacity to roast 24 chickens or 80 pounds of beef at once. Each section is a complete unit in itself, permitting their arrangement in any desired order. If the sections were placed in a single row the range would be 30 ft. in length. The range is of steel throughout, with polished trimmings, and is superior in workmanship and durability to coal and gas ranges. The top equipment comprises the following units, each controlled by a separate switch with ruby pilot light and three adjustable heats. Seven 10-in. by 24-in. hotel griddles with rims, two 18-in. by 24-in. flat griddles or hot plates, one 12-in. by 18-in. corrugated surface broiler, one 12-in. frying kettle for deep fat, one 6-slice hotel type bread toaster, five 15-in., two 10-in. and five 8-in. hot plates.

The heating units are of the enamel type and the controlling switches are conveniently mounted on the front of the range at a height providing for minimum labor in handling. The estimated maximum demand is 46 kw., and on the basis of 0.25 kw.-hour per day per person the energy consumption will be 259 kw.-hours per day, or 7,500 per month, making the cost of electricity, on a 2-cent rate, $150 per month. This is offset against the cost of coal, cost of handling coal and ashes and additional attendance required for handling a coal outfit. There will also be decided savings in food due to superior cooking as compared with coal or gas ranges, avoiding waste due to over and under cooking, excessive shrinkage, etc., which in many installations amounts to more than the cost of fuel.

UNIQUE CALL SYSTEM FOR BUILDINGS.

In an office building of 22 stories that is kept in good condition, there is a staff of mechanics constantly in service. To find the foreman of any of these gangs is a problem, since he may be in any of a dozen or so rooms. In the superintendent's office is a little switchboard with three flush switches each controlling a lamp on the board for a pilot and one of three over the freight elevator door on every floor, says B. R. Browne, in *Electrical Review and Western Electrician*. Red, white and green lamps are used. Each foreman has his call; for instance, the electrician's is green, the carpenter's red and white, the head porter's white, and so on. When the superintendent wishes to speak to any of the staff he calls by this lamp signal and the party called plugs a pocket telephone set that he carries into a little flush receptacle beside the elevator door on any floor and he is then in communication with the chief.

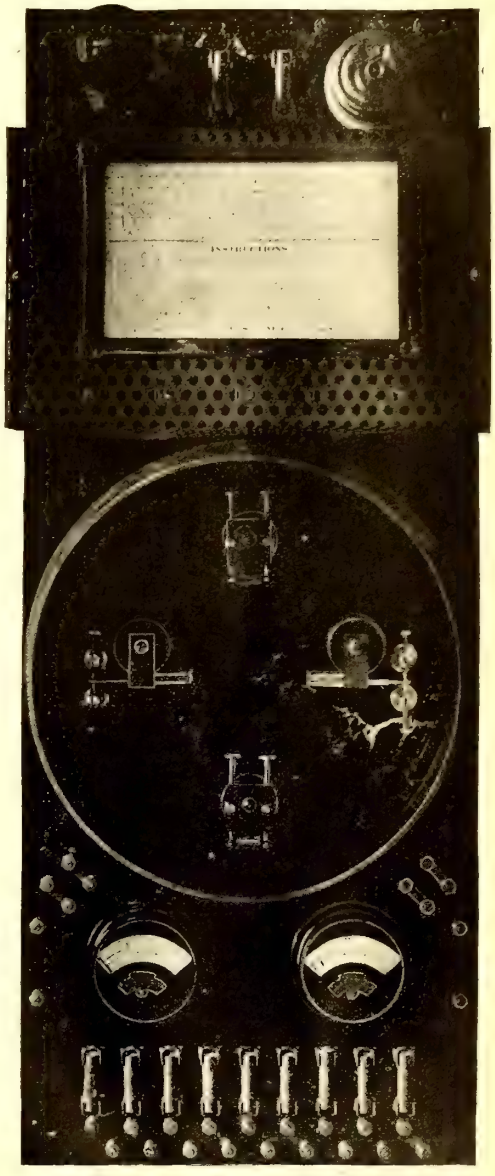
The whole thing is so simple and flexible that it could readily be adapted to suit any requirement of factory or office building.

By being placed near the freight elevator it is easy to wire, using conduit and condulet fittings. All that is exposed comprises three condulet receptacles over the door, the conduit running up the shaft and a short extension coming through the wall on each floor.

The pilot board is placed beside the telephone private branch exchange in the office of the building, so that the operator cuts off the signal when the conversation is closed. The lights are conspicuous enough for some of the staff to surely see, and yet are not as objectionable as a bell or other call in a public building. All stock materials can be used.

THE POTENTIOSTAT FOR HOSPITAL CALLING PURPOSES.

From time to time many clever and unique devices have appeared for use in hospitals, particularly for calling the nurse or the doctor, as the case may be. This new device, however, combines all the good points of all these ideas and has not a few original features.



Primarily it consists of an automatic storage battery charging board and a push button of novel design, placed at the side of the bed. The apparatus is mounted in front of the nurse's or doctor's desk and miniature incandescent electric bulbs are placed on the board and operate in connection with the annunciator.

The complete system in outline works as follows: Whenever the patient desires the services of the nurse he merely presses the push button, which lights a certain lamp on the board and the annunciator indicates at once which patient is calling. The lamp remains lighted until the nurse answers the call. After attending to the patient she merely pushes another button placed near the bed, which extinguishes the light.

Practically all of the previous signal systems were operated on low voltage current, but the method of reducing same from 110 volts to the required voltage being very inefficient, made the operation of these systems on a large scale very expensive. This decided weakness and consequent expense was brought to the attention of several engineers and many devices were developed, but with very little success until an instrument was perfected for reducing high voltage to a lower voltage economically.

This is called the Potentiostat by its manufacturers and is herewith shown. In detail it consists of a number of storage batteries which supply the current to the lamps or bulbs. The batteries are charged automatically from time to time from the regular street mains. The charge is controlled by an automatic circuit breaker observed in the center of the Potentiostat. A volt-meter and ammeter are provided for determining the exact condition of the cells.

The system here described has power enough to handle 365,000 bells or lamps, which is a good deal more than it will ever be called upon to operate most probably.

The Potentiostat Can Ring 365,000 Call Bells or Signal Lamps, the Latter Being Used for Hospital Service.

The advantages of this new system are apparent when it is considered that the light will continue to burn as long as the call is not answered, and any delinquency on the part of the attendant will be readily noticeable by the undue length of time which the lamp operates. This device has proven its value repeatedly at various hospitals where it has been installed by increasing the quality of the service.

New Arc Lamp Consumes No Electrodes

This New Arc Lamp Marks the Greatest Advance in Illuminants in a Decade

SINCE the advent of the gas-filled incandescent lamp bulb, science has led us to believe that the only step remaining to make an ideal illuminating unit would be the invention of cold light. However,

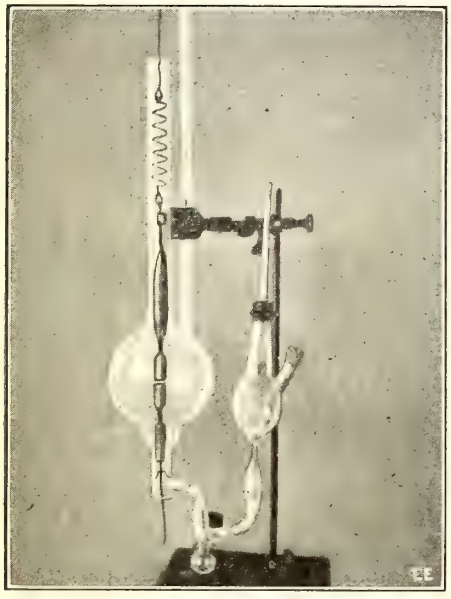


Fig. 1. Appearance of New Arc Lamp That Does Not Consume Electrodes.

there has appeared a new and novel arc light which burns in a gas-filled chamber. It may be remarked that the arc lamp was the first electric lamp of any practical importance.

This new lamp, the invention of W. A. Darrah, is the outcome of a series of elaborate and painstaking experiments on various forms of electrodes and different mixtures of gases in the chamber. In its present form it consists of two tungsten electrodes which are not consumed, and the arc burns in an atmosphere of certain gases. The lamp is shown in Fig. 1, and, as will be seen, comprises a glass bulb containing a predetermined amount of gas (a mixture of titanium tetrachloride and bromine gas), and having supported from the opposite ends the two tungsten electrodes.

The working parts of this lamp are indicated in Fig. 2, and the general idea of its operation can be obtained therefrom. The large glass bulb is approximately the size of an ordinary incandescent lamp and has mounted at the lower end a solid rod of tungsten ¼ inch in diameter. The connection to this rod is made through a small tungsten wire. The upper neck of the tube supports a sliding iron core in which is mounted the other tungsten electrode. A flexible conductor connects the upper electrode with the seal in the globe, and a coil of wire around the iron core (see diagram) of the upper electrode serves to start the arc and regulate same. This regulation is very easily accomplished, due to the fact that the electrodes are not consumed, and, being automatic, the lamp may be operated from an ordinary switch.

The effect of gases on the stability of an arc was determined by Poulsen in connection with his experiments with arcs for wireless telephony and undamped wave radio transmission. The same effect is here obtained by the gases used inside of the globe. They render the arc intensely luminous and very steady. The gases themselves are consumed at a very slow rate, and thus the globe is not blackened. The lamp requires no more attention than an ordinary incandescent bulb.

In operation this lamp gives an arc from 2 to 5 inches long, depending, of course, upon the voltage, and the arc proper is about ⅛ inch in diameter. It has the appearance of a bright, white incandescent filament. It does not flicker like an ordinary carbon arc in the air, and the intense light has a spectrum almost identical to that of the north sky on the afternoon of a clear day. In other words, this means that the lamp gives a light not unlike daylight, the only difference in the spectrum being due to the slight absorption of the various spectrum lines by the vapor in the lamp.

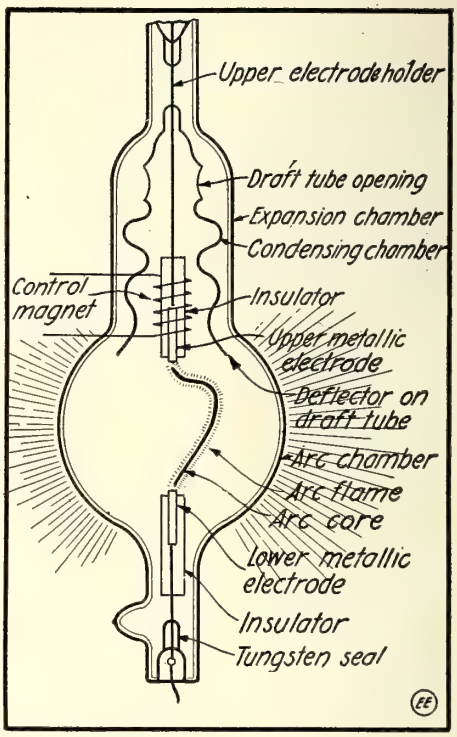

Fig. 2. Diagrammatic View of New Gas-Filled Arc Lamp, Which Seems to Possess Great Promise.

Although this arc lamp is still in more or less of an experimental stage, it gives considerable promise of supplanting the modern incandescent light and becoming a large factor in the illumination of the near future.

ELECTRIC MOTOR BUCKETS, THE LATEST.

Electric motors have been adapted to many diversified requirements in the industrial line, and it seems as though these

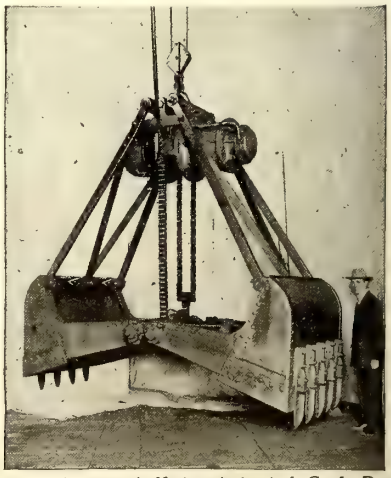
Fig. 1. Small Grab Bucket Opened and Closed by Electric Motor Mounted Directly on Same.

adaptations had come almost to an end, but every day there is found some new and worth-while application of the electric motor, which has so far remained unsurpassed for high operating efficiency, cleanliness and ease of control.

One of the latest uses of the electric motor is its incorporation in the design of large grab-buckets, as the illustrations herewith portray. Fig. 1 shows a large clam shell bucket suitable for scooping up coal, dirt, or other loose material, and the operator is seen plugging in the flexible cable leading down from the crane into the motor terminal block. As perceived, the motor operates the bucket jaws through the medium of a short, but powerful chain belt. The many advantages of this arrangement are self-evident, as any extended length of control cables or ropes which have caused immeasurable annoyances in the past are done away with. The motor in this case can be operated by the man in charge of the crane or derrick, to which the grab-bucket is attached or where the bucket is used in shops and manufacturing plants on a traveling rail, a short switch chain extending from the motor enables anyone to operate same with ease and dispatch.

Fig. 2 shows a powerful electric motor bucket equipped with steel teeth and intended for digging in hard materials, such as dirt mixed with rocks, etc. These newly devised buckets are supplied in a large variety of designs and special types are furnished whenever necessary. The flexible electric cable supplying the motor current, it may be mentioned, is wound up on a spring-propelled drum attached to the crane or derrick.

The many advantages accruing from this distinct and valuable advance in engineering design is at once apparent to anyone who has ever watched a grab-bucket at work. No end of trouble is encountered



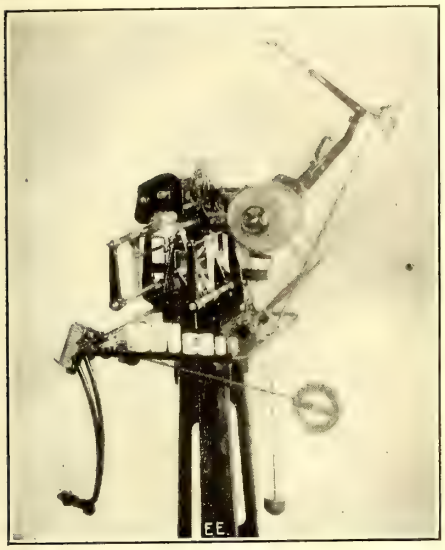


Fig. 2. Powerful Motor-Actuated Grab Bucket Fitted with Teeth.

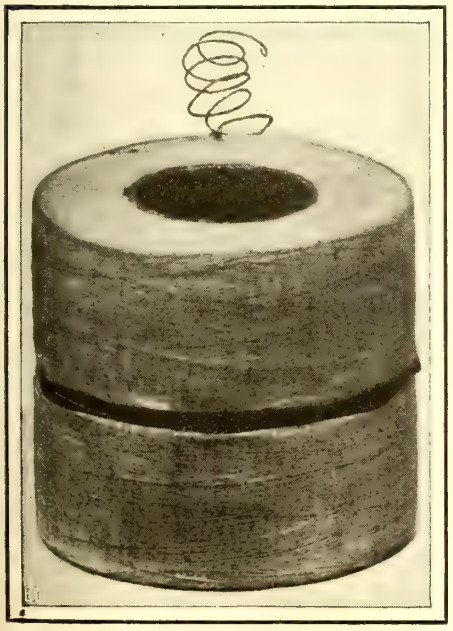
regularly in the operation of cable-controlled buckets of this type. Again, they often fail to close fully, but not so with the motor-operated type, as it closes the jaws tightly every time.

A NOVEL ELECTRIC COIL WINDING MACHINE.

By Frank C. Perkins.



The accompanying illustration shows a novel electric coil winding machine developed at Boston, Mass. It occupies a floor space of 2 feet 6 inches by 2 feet 2 inches

Clever Machine That Automatically Crosswinds Magnet Coils of Self-Supporting Form.

and has a weight of 300 pounds. The driving pulley speed is 500 to 2,000 r.p.m. and it winds any length of coil. This electric coil machine is used for winding magnet coils by the Universal cross winding method, which has given excellent results in winding many forms of coils.

Valuable economic results have been secured through the use of the machine in winding coils automatically, in place of by hand or with somewhat crude mechanical appliances. It has been found that while for some kinds of magnets the cross-wound coil is admirably adapted, there are many forms of coil for which cross-winding is not adaptable. Experiments were begun in winding concentric coils, the wire being

Typical Crosswise Wound Coil, Made on Machine Above Pictured.

placed side by side similarly to spool thread. As will be obvious the difficulty with such coils arises from want of cohesion, without supporting heads. The element lacking was finally supplied by the addition of fine cotton yarn wound simultaneously with the wire, by the cross-wind system.

The coil thus produced is unique, and extensive use of this arrangement has demonstrated its value over the entire field of electrical magnets. The coils formed by the magnet machines are symmetrical, strong, compact and durable. These coils are wound either in cylindrical or in rectangular form, with or without cores. When wound without cores, they can be compressed into any desired shape without impairing their efficiency.

In winding this form of coil, a fine cotton yarn is interwoven with the wire, which may be either enameled or insulated with silk, cotton or other suitable material. The plane of the wire convolutions is at right angles to the axis of the coil, while the plane of the cotton strands lies obliquely to the axis, the entire mass being bound together so that the finished coil is practically indestructible either from external or internal stress.

In winding these coils the yarn is carried axially to a greater distance than the wire convolutions, thus forming an electrical and mechanical protection at both ends of the coil. After the requisite number of convolutions of wire have been made, the winding of the yarn may continue and entirely cover and surround the wire. The resulting coil is completely armored, similarly to a taped coil, rendering a separate covering operation unnecessary. In the winding process the yarn is so disposed that the convolutions of wire are slightly separated; and while a complete insulation between the several layers of wire is not obtained, there is secured a graded insulation which is thickest where the potential difference in voltage is highest.

It is stated that the amount of insulation may be varied, depending, naturally, upon the design of the coil. The interposing of the yarns between the layers and turns of wire facilitates the impregnation of the coils with the various insulating compounds. The mass of yarn between the layers and between the coils also forms a cushion, making an elastic coil, so that when high voltages or heavy currents are passed through, the coil is not ruptured or destroyed.

It has been found that the space factor is high and the air gap low, particularly so when this coil made of enameled wire is compared with coils wound with cotton or silk covered wire. In addition to the many electrical and mechanical advantages secured by this form of coil, a notable feature is the facility with which coils may be duplicated, giving exactly the same result in every coil wound. Coils wound as described have eliminated therefrom all defects, perfect units being produced.

It is of interest to note that the machine illustrated is automatic in operation. It is provided with a counter which can be set to the predetermined number of convolutions required, the machine stopping when these have been made, therefore insuring the same resistance and uniformity of size in all coils.

ELECTRICAL PRODUCTION OF OXYGEN AND HYDROGEN.

Oxygen and hydrogen are at present produced by two methods, viz., by the decomposition of potassium chlorate and manganese dioxide and by the decomposition of water by an electric current. The latter method is cheaper and a much purer gas is produced. The only substances needed for generating the gases is distilled water and a small quantity of potash for increasing the conductivity of the electrolyte.

Our photograph, Fig. 1, shows a commercial generator unit designed for generating the above mentioned gases. Each of these units is capable of delivering 3.2 cubic feet of oxygen and 6.4 cubic feet of hydrogen per mean hour and 4 cubic feet of oxygen and 8 cubic feet of hydrogen per kilowatt-hour.

These generators operate on 400 amperes at 2 volts D.C., or a little over one

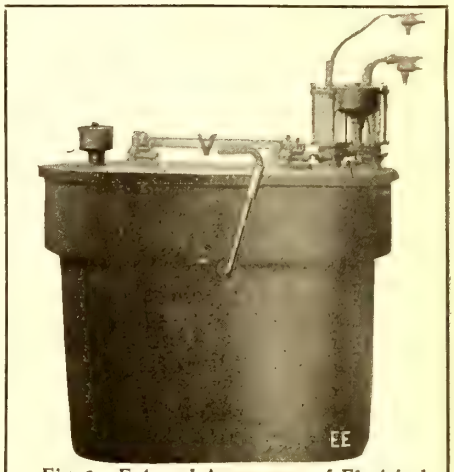


Fig. 1. External Appearance of Electrical Oxygen Generator.

horse-power of electrical energy. The gases are produced in compartments perfectly separated and, therefore, are very pure; the oxygen testing 99.6 per cent., while the hydrogen tests 99.8 per cent., which is undoubtedly pure enough for any use, even for medicinal work.

The generators are built entirely of iron. Fig. 2 depicts a schematic diagram of one of these units. At A is the oxygen off-take and at B the hydrogen off-take, which are connected to two separate glass tubes C, C, called the indicators and pressure equalizers. The negative terminal connects to the frame of the unit. The water is poured into the cell through cup F. In order that the gases do not escape into the air or mix up with each other within the cell, a hydraulic joint, G, is provided. The positive or anode pole is separated from the cathode by an asbestos dia-

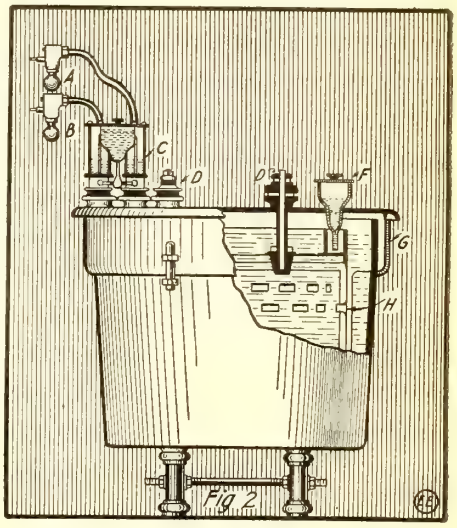

Fig. 2. Detailed View of Oxygen Generator.

phragm, H, which is porous. The complete unit is supported on porcelain insulators.

Mysteries of Matter

By John Candee Dean

WHAT do we actually know about matter today? What we partly know and what we do not know is covered at some length in the following discourse by Mr. John Candee Dean. Most of us have heard of or are somewhat familiar with the division of matter known as the atom. The electron is the latest sub-division of matter and an atom has been estimated to be 100,000 times as large as an electron. In order to bring the electron up to the size of Lord Kelvin's magnified atoms it would be necessary to magnify a drop of water to 100,000 times the size of the earth. Here is something to think about! For when all the peculiarities and characteristics governing the formation and activities of the electron are once known, then we shall be indeed a long way on the road to the solution of many scientific and industrial problems which at present have baffled our best technicians. The electron, according to the latest researches, apparently lives in a world all its own, which is as interesting in its study as the life of the average human.

IN the study of the vast, or of the minute, the imagination is incapable of comprehending the spaces involved. When we say that the sun is more than a million times larger than the earth, the statement does not present a mental picture of the sun's magnitude. A better conception of the sun's immensity can be obtained by saying that if the earth were placed in the center of a spherical shell, with a diameter equal to that of the sun, the moon's orbit would be a little more than half way between the earth and the shell of the sphere. But sizes of all things are relative. The magnitude of the sun is insignificant compared with some of the fixed stars. Professor Kapteyn estimates that the red star Antares, in the heart of the Scorpion, is 3,400 times as brilliant as the sun. The diameter of Antares is estimated to be 160 million miles, or nearly as great as the orbit of the earth.

We meet with the same difficulties in attempting to comprehend the spaces occupied by molecules, atoms and electrons. Lord Kelvin said that if we could magnify a drop of water to the size of the earth, the atoms then might appear to be somewhat smaller than cricket balls. The average atom has been estimated to be 100,000 times as large as the electron. Now to bring the electron up to the size of Kelvin's magnified atoms, it would be necessary to magnify a drop of water to 100,000 times the size of the earth.

For nearly 100 years Dalton's atom kept its place in the theory of the structure of matter. This atom was supposed to be the ultimate particle of matter, and stability was believed to be an essential characteristic of all the elements. At the beginning of the present century, the old theory of the indivisible atom, and of the stability of the elements, was upset by the discovery that certain rare elements were disintegrating, and changing, by throwing off particles much smaller than atoms. It must not be assumed that this discovery demolishes the atom. It does not. The atom continues to be the unit that enters into all chemical combinations. The hydrogen atom was formerly the smallest particle known to science. Now the smallest particle known to science is the electron, whose weight is one seventeen-hundredth part of the hydrogen atom.

Herbert Spencer said, in substance, that organic progress consists in a change from the homogeneous to the heterogeneous, and this law of progress is the law of all progress. He said, "From the earliest traceable cosmical changes, down to the latest results of civilization, we shall find that the transformation of the homogeneous into the heterogeneous is that in which progress consists." No two elements have atoms of the same size or weight, and each of the different elements has strong individual characteristics. Atoms are therefore heterogeneous, and according to Spencer's law they must have been evolved from a lower stage of matter. Now electrons appear to be absolutely homogeneous, since all electrons are of the same weight or mass, carry the same electric charge, and always turn out to be the same thing, regardless of the metal that forms the negative electrode, or the gas from which they are derived. Hence, according to the Spencerian law, they should be the primal substance from which matter is evolved.

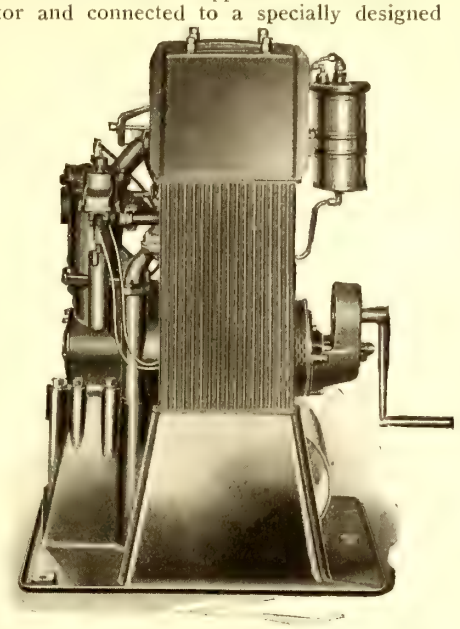
Stability is no longer regarded as an essential characteristic of the elements. The element radium disintegrates by the explosion of its atoms. The primary elements subject to disintegration by atomic explosions are uranium, actinium and thorium. Radium is derived from uranium in consequence of its throwing off three atoms of helium. Hydrogen (1.008) is the lightest of the elements. Uranium is the heaviest. Its atom is 238.5 times as heavy as hydrogen. The atomic weight of helium is 4. Three atoms of helium would be 12, hence uranium (238.5) — helium (12) = radium (226.5). The atomic weight of radium is 226.4. The small difference is probably due to the loss of electrons during the change. Radium disintegrates by the breaking up of its atoms, each radium atom hurling off one particle of helium, and one of niton. The change is as follows: Radium (226.4) — helium (4) = niton (222.4). Therefore, the atomic weight of niton is 222.4.

The explosion of the atoms of radium appears to be as complete as that of a steam boiler; the whole of the atom bursts into gases. The light atoms of helium, that form, are shot into space with a velocity of more than 10,000 miles a second and the heavy residual atoms of niton acquire sufficient velocity, in consequence of the ejection of the helium, to escape and be deposited on bodies in the neighborhood. The expelled helium atoms are called Alpha rays. There is an inexpensive little instrument, called the Spinthariscope, which is arranged with a minute particle of radium in front of a zinc sulphide screen. On looking into the instrument one can see the helium atoms bombarding the screen, each atom producing a minute scintillation, the hundreds of points of light making the screen sparkle like the stars in the Milky Way. The helium atoms are so minute that the bombardment of the screen could go on for hundreds of years without any sensible diminution of the particle of radium.

Radium also emits powerful Beta rays, which consist of electrons flying out with a velocity of 100,000 miles a second, capable of penetrating thin plates of metal. A third radiation, called Gamma rays, originate in the impact of the Beta rays. They are really X-rays of such strength that shadow-graphs can be made with them through eight inches of solid lead. This radiating power is an automatic property which cannot be produced artificially. Radium is a very heavy metal. Heavier than gold, mercury, lead or any material with which we are familiar. It disintegrates very slowly. Its half period of decay is 1,760 years. If a gram of radium were put away for 1,760 years, only half a gram would remain at the end of that time; in 3,500 years one-fourth gram, and in 7,000 years one-eighth gram would remain. The half period of uranium is roughly estimated at seven billion years, while that of thorium, another radio-active element, at ten billion years. An attempt has been made to estimate the age of the earth from these slowly decaying elements.

As already stated, the emanation of radium is niton, an inert substance which forms no salts. Niton's half period of decay is only four days, and its emanation is changed to a new type of matter called Radium A. Each second a definite fraction of the number of atoms present break up, and the process of degeneration continues through a number of distinct unstable forms, called Radium A, B, C, D, E, F. Radium F is also called Polonium, an intensely radio-active substance with an atomic weight of 210.4. By throwing off one atom of helium its weight changes to a substance with an atomic weight of 206.4 which is close to that of lead, hence it is probable that lead is the final product of the radium series. Twenty-six so-called elements are derived from the automatic breaking up of uranium, thorium and actinium; 16 of which are formed by throwing off of helium atoms, and are therefore real elements. Ten are formed by the emission of electrons and therefore are allotropes or pseudo-elements. It is by the ejection of full-sized atoms that substances of different chemical properties and valency result. We frequently have our attention drawn to the enormous energy stored in radium and its emanations. Sir Wm. Ramsay states that the heat which niton parts with during its disintegration is equal to 3,500,000 times the energy available by the explosion of an equal volume of detonating gas. The principal part of this energy comes from the expulsion of helium atoms. He also says: "If radium were to evolve its stored-up energy at the same rate that gun-cotton does, we would have an undreamed of explosive, provided always that a sufficient supply of radium were forthcoming," and Sir J. J. Thomson startles us with the statement that the atomic energy stored in an ounce of chlorine, "Is about the amount of work required to keep the *Mauritania* going at full speed for a week." He further tells us that to split up an atom of one element into different kinds of atoms would involve enormous transformations of energy, "In fact the explosion of the atoms in a few pounds of material, might be sufficient to shatter a continent!"

The electromagnetic unit is an electric current of one ampere flowing for ten seconds. A 16 candle-power, 110 volt, carbon-filament, electric lamp requires a current



"UNI-LECTRIC" AN IDEAL PRIVATE LIGHTING SYSTEM.

A few years ago "private electric lighting plants" were rated as a luxury which only the very wealthy could enjoy. Now, however, the introduction of the "Uni-Lectric" lighting, cooking and power system has proved that not only is a complete electric lighting plant in domestic size available at a reasonable cost, but that it is available without the elaborate and complex mechanism of the ordinary individual electric system. Such being the case, it is expected that the "Uni-Lectric" will be the forerunner of a complete revolution in private lighting methods in communities where current from a central power station is not available.

The "Uni-Lectric" lighting system is a recent invention perfected by Warren Noble, well-known consulting engineer and designer. Its chief claim to distinction lies in the fact that the entire generating device is built in a single small and compact unit, 42 inches in height, 25 inches in length, and 24 inches in width. Hence the name "Uni-Lectric."

The device itself, which differs radically from anything else of the sort yet perfected, consists of a small four-stroke motor of the high efficiency type, operated by gasoline or other similar fuel, and direct-connected to a specially constructed electric generator. This generator develops a standard 110-volt direct current. It is cooled by a forced draft induced by fan blades on the flywheel of the motor, so that even when run for hours with an overload of 100 per cent. it will not overheat.

The fuel tank is supported above the motor and connected to a specially designed

The "Uni-Lectric" Lighting Plant is Very Rugged and Self-Contained, Comprising Dynamo and Gasoline Engine.

carbureter. The throttle is operated by a special electric governor regulating the speed according to the load and maintaining a constant voltage with all varying loads. The ignition is by high tension magneto with fixed spark.

No switchboard or batteries of any kind are used. No rheostat or volt meter is required. Two terminals are provided on the machine for attachment to the two feed wires leading to the lights. There is no possibility of misconnecting, as either wire may be attached to either terminal. The normal capacity of the machine is rated at 500 watts, with an overload capacity up to 600 or 800, so that from 30 to 60 Tungsten lights, depending on the wattage, may be carried on the line.

As designed the "Uni-Lectric" is said to be absolutely automatic and foolproof. It is started by a turn of the high-geared crank, and it is noteworthy that the starting gears are never in operation except when the handle is turned. The opening of the magneto switch stops the operation of the machine. All moving parts are inclosed. The motor and generator are so perfectly balanced that no foundation is required, and the machine need not even be bolted to the floor.

FRENCH DOG REPORTS BY TELEPHONE.

According to the *Gazette de France*, a certain French regiment possesses a dog which is sent out from advanced sentry posts at night with a telephone strapped over his mouth and a wire connecting the instrument with the post. If the dog hears the Germans approaching it barks quietly into the telephone.

---

of one-half ampere. Therefore, such a lamp consumes one electromagnetic unit in 20 seconds. The agitation produced by the crowding together of millions of swiftly passing electrons gives rise to the brilliant light of the filament. The electric energy is so concentrated in the electrons that a mass of them equivalent to a mass of *one ounce* would light 300 of these lamps to their full candle-power, night and day, for a year.

In spite of the minuteness of atoms Rutherford has been able to detect the presence of a single atom of helium. He employed a partially exhausted vessel having a tiny hole, through which, by ingenious apparatus, single atoms of helium were shot. These atoms are expelled from radium with a velocity of more than 10,000 miles a second, striking and breaking up the gaseous molecules in the vessel, producing positively and negatively charged ions, which for an instant permit a current of electricity to pass. A current measuring instrument in the line records the entrance of the atom, enabling the observer to count each one as it enters.

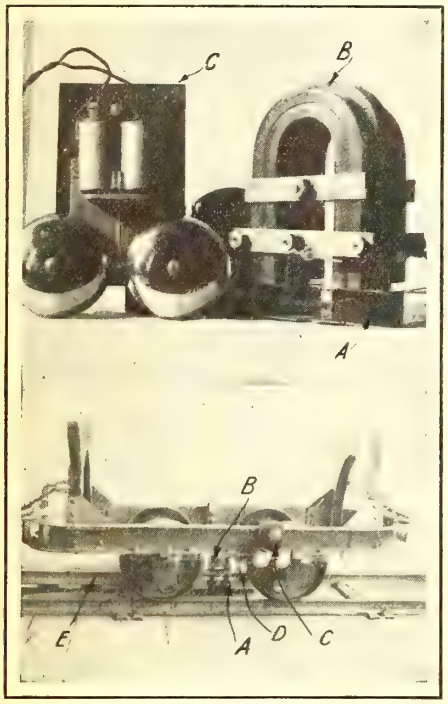
We appear to be getting back to Franklin's single fluid theory of electricity. The electric current is believed to be a movement of negative electrons through a conductor, from the negative to the positive, instead of flowing from the positive to the negative, as was formerly supposed. Many scientists believe that negative electricity is the only kind. Positive electricity arises from a lack of electrons. For example, a positively charged helium atom is merely a helium atom that has temporarily lost two of its electrons. In theory the negative electron is not a particle negatively charged, but is in itself a negative charge. This is equivalent to saying that matter is wholly electrical. The electron enters into the structure of the atom, but is the weight of the atom due entirely to the mass of the electron? It is claimed that the electron has no mass in itself. Its apparent weight is due to the adhering ether which it drags along, as it shoots through space. It is like stirring a bucket of water with a cane, a small quantity of the fluid will temporarily adhere to the cane and be carried along with it.

Nature is more marvelous, more interesting and more beautiful than anything that the imagination can produce. The great French astronomer and scientist, Henri Poincaré, tells us that the scientist does not study nature because it is useful. He studies it because it pleases him, and it pleases him because it is beautiful. He says, "Were nature not beautiful, she would not be worth knowing, life would not be worth living. I do not mean here, of course, that beauty which impresses the senses, the beauty of qualities and appearances; not that I despise it—far from it; but that has naught to do with science; I mean that subtler beauty of the harmonious order of the parts which pure intellect appreciates."

It is a mistake to suppose that knowledge of breaking up of atoms into smaller particles originated with the discovery of radium. As far back as 1873 Sir Norman Lockyer suggested that many difficulties of the laboratory would vanish if we conceded that atoms could be broken up into much smaller particles. In 1890 he published "Inorganic Evolution as Studied by Spectral Analysis," in which he says, "Science now has to consider masses much smaller than the atom of hydrogen." In the study of the hottest stars he found himself in the presence of furnaces of transcendental temperature shielded by their vastness from the distracting phenomena which were present in the laboratory.

He classified the fixed stars in the order of their temperatures. Stars of the hottest class he called Argonian from the star Gamma of the constellation of Argo Navis, which has a temperature estimated by him at 50,000 degrees F. Gamma Argus contained a set of spectral lines not before recognized and he concluded that they indicated a new element connected with hydrogen. He called the new element protohydrogen, because of the relation of its lines to those of the proto-metallic lines. The Argonian stars are now called helium stars; they show but few elements. Protohydrogen, helium, asterium and proto-calcium are conspicuous. Lockyer tells us that the high temperature at which protohydrogen appears, is not the end of the simplification of stellar transcendental temperature. "The work of the dissociation of the atom carried on under our eyes in the hottest stars, is quite impossible in our laboratories." He says, "At higher temperatures the chemical units with which we work at low temperatures are broken up into smaller masses, explains the spectral phenomena observed, not only in our laboratories, but in the sun and stars. The final breaking up by heat must be the earliest chemical forms."

Heat is a motion of the atoms of matter, and a fall of temperature slows down this motion, but man's ingenuity has not yet brought a single atom to a state of rest. The temperature of a body varies as the square of the amplitude of vibration of its atoms. If all the heat of a body could be abstracted its atoms would cease to vibrate. Increase of heat accelerates atomic motion until a critical velocity is attained that overthrows the affinities which hold the atoms in chemical combinations. At a temperature of 4,000° F. the existence of water is no longer possible, not even in the form of steam. Its molecules no longer cohere, because of their energetic motion, and they dissociate into hydrogen and oxygen gases.



The heat of the sun is probably sufficient to dissociate all chemical combinations, consequently interior solar matter is in its monatomic, or elementary condition, and much of it may be in the electronic state. Perhaps there is a critical or maximum temperature for all matter, where the violence of the motion of clashing atoms causes them to break up into electrons. In stars of the highest temperature like Gamma Argus, or Zeta Puppis, the critical state has probably been reached and the greater part of their matter is in the form of electrons. When matter is in its hot-

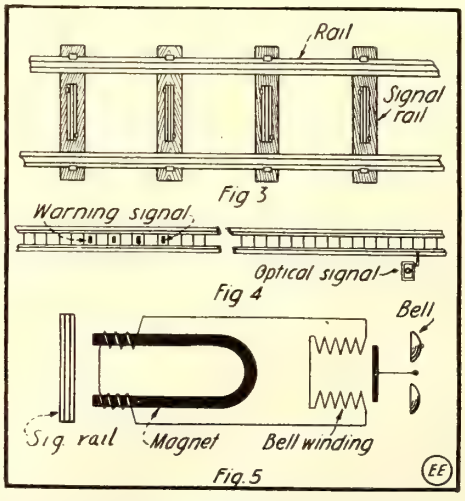
New Electric Signal for Locomotives

The subject of safety on railway trains is of vital importance, especially at present, when railroad travel is more extensive than it has ever been.

The main cause of accidents which arise now and then is due mainly to the negligence on the part of the engineer or switchman, and sometimes also to the improper working conditions of the semaphore. The cause is due to the engineer in that he does not watch carefully for signal blocks, although sometimes this is not rightly called the fault of the engineer, as it is often necessary for him to adjust some device in the locomotive cab while the train is in motion. Consequently his attention is drawn away from the road, which may mean a wreck or collision.

Above (Fig. 1): Shows Details of Magneto Ringer for Locomotive Signal. Below (Fig. 2): How Signal Bell Is Attached to Locomotive Frame.



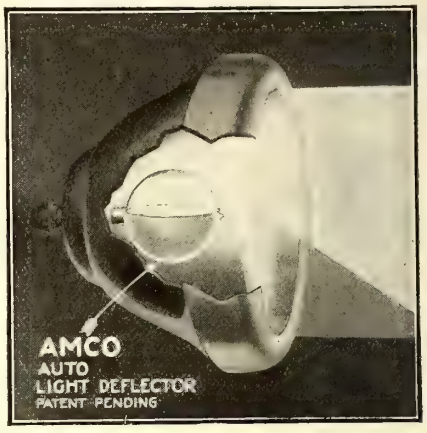
Suppose now a device is installed on the track before the block signal is reached, say about a mile or so, which, when the train reaches it, will cause a bell to ring in the cab, thus calling to the attention of the engineer that he is approaching a block and should be on the lookout for the signal which informs him of the condition of the road, of course.

Various devices have been developed in the past for arresting the attention of the man driving the locomotive, but none of them have proved a success, as they invariably employed contacts on the engine and track, and also some means of supplying current, such as batteries and dynamo. Now everyone knows that whenever batteries and sliding contacts in any electrical instruments are used that the condition of it will not be absolutely reliable. Practically all the devices for calling purposes on railways being employed to-day are impractical, due to the fact that they use sliding contacts and batteries or a generator, which require a great deal of care to keep the instrument in proper working condition and to which very little time can be given in railway work, generally speaking.

Now every student of electricity knows that whenever an electro-magnet is connected to a galvanometer and its field disturbed by some magnetic body, either by revolving same near the electro-magnet or by drawing it to and away from it, this action on the electro-magnet will cause a current of electricity to be produced in the winding, and this will in turn act upon the needle of a galvanometer. This is the exact principle upon which our present dynamos work.

This principle is used advantageously by A. Christian Berger (the originator and inventor of the submarine wireless system which was described in the August, 1915, issue of this journal) in developing a new electric railway signaling device, which employs only three simple parts and which does not, moreover, require any attention, as there are no sliding contacts or batteries used. His apparatus, which is shown in Fig. 1, consists of an electro-magnet A mounted on the poles of a powerful steel permanent magnet B. The electro-magnet is connected to an alternating current bell C (being of a type that does not employ any contacts), but which operates on the change of direction in the current.

The generating magnet A is placed underneath the locomotive as shown in Fig. 2, which is a photograph of an experimental train utilizing Mr. Berger's invention. The alternating current bell C is connected to magnet A by means of a wire D. The flux in the generator AB is changed by a series of iron strips E, laid between the track as perceived. In practise a number of short pieces of standard rails are laid in the center of the track and at right angles to it, as shown in Fig. 3, which is a schematic drawing of the track. The operation is as follows: When the train is passing over these intermittent center rails the magnetic flux in the electro-magnet is increased and decreased successively, thereby producing an alternating current in the coil, which in turn operates the polarized bell. The faster the train passes over these rails the stronger the bell will ring. If the number of rails is increased the same effect is produced. As will be seen, the operation is simple, neither contacts nor batteries are employed and there is nothing to wear out. The location of these rails would depend upon the condition of the roadbed. Fig. 4 shows diagrammatically the position in which they are placed. The connection of both of the instruments is depicted in Fig. 5.



How the Berger Magneto Locomotive Signal Operates. Changes in Magnetism Ring Bell. No Battery Used.

This is another achievement in the development of apparatus for the prevention of accidents. "Safety first."

NEW AUTO HEAD-LAMP REFLECTOR.

The blinding glare produced by automobile headlights has been the subject of much discussion and legal argument. In some cases there have been passed ordinances controlling this problem. To reduce the blinding glare so produced, which has been the cause of many otherwise avoidable accidents, there has been recently marketed a unique device shown in the accompanying illustration. This consists of a hemi-spherical shell enameled white inside, which readily snaps over the electric light bulb in any such headlight. Its function is to deflect all the light rays to the upper half of the lamp reflector, thus throwing them outward and downward. It is guaranteed to meet the requirements of all State laws and regulations, and has received official sanction by the department of motor vehicles for the State of New Jersey. It should find general and extended use by all motorists, as the price is very nominal indeed, and as is generally known, the owner of a motor car does not care to spend any more than is absolutely necessary on such attachments as these.

Novel Auto Head-Lamp Shield to Reduce Glare.

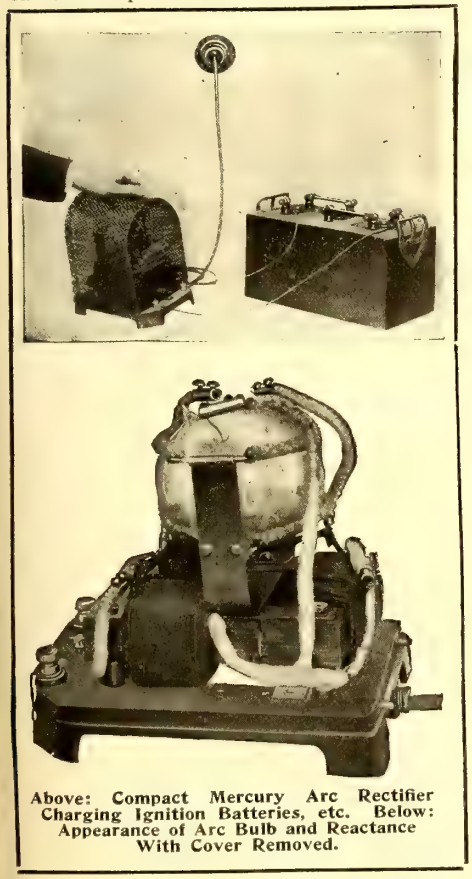
ARMY PURSUES BANDITS WITH WIRELESS.

With the arrival at Mission, Texas, of Company B, Signal Corps, from Texas City, the American border patrol forces in the Lower Rio Grande Valley were able to pursue bandit raiders with the aid of wireless, it was announced at Fort Sam Houston.

Company B has four sets of portable wireless telegraph outfits, and there are already three pack trains in the Brownsville district. This will make it possible for Colonel Blocksom, commanding the district, to station one detachment of the signal company with a wireless outfit at Mission, the operating center of recent trouble, and have three detachments, each with wireless and pack train detail, ready for immediate field service.

The advantages of the new system of communication can hardly be estimated. Wire service, both telephone and telegraph, in the district is quite limited and even this has been often disabled by the raiders, who cut all wires as a preliminary to attacking any section. The result has been that while there have been an abundance of troops in the field for several weeks, they have been unable to surround a single band of raiders and prevent their escape because of the lack of communication and the densely brushy character of the country.

Do you know of some interesting electrical device, appliance or machine in your vicinity? Why not send us a picture of it?



MERCURY ARC RECTIFIER FOR CHARGING SMALL BATTERIES.

A new and inexpensive mercury arc rectifier is just being marketed by one of the large electrical manufacturers for charging small storage batteries, such as those commonly used for starting, lighting and ignition current in gasoline automobiles and motor boats, for operating electric bells, for electro-plating and for numerous other uses where not over 5 amperes, 15 volts direct current is required and where only alternating current is available.

The new rectifier consists of a metal base, on which are mounted the necessary reactance coils and the rectifier tube in a suitable cover, the whole being encased in perforated sheet metal. It is designed for charging one three-cell, one six-cell or two three-cell batteries as required, and is automatic in that it is self-adjusting to any of these three conditions. In fact, the rectifier may be connected to a single-cell battery and will charge it at the rate of approximately 6 amperes from 110-volt alternating-current supply.

This type of rectifier is furnished for 60, 50, 40, 30 or 25 cycles, 110-volt alternating-current circuits. It is exceedingly compact, the outside dimensions being, roughly: Width, 6½ inches; depth, 9½ inches, and height, 11 inches. The total weight of the 60-cycle rectifier is approximately 15 pounds; therefore it may be transported from place to place in a garage, rendering unnecessary the removal of the battery from the car.

The rectifier is completely self-contained and requires no mechanical ability either to install or operate it. It is so designed that it will maintain a fairly constant current as the voltage of the battery rises. It is very easily started, simply by screwing the flexible lead attaching plug with which it is furnished into any convenient alternating-current lamp socket and connecting the two

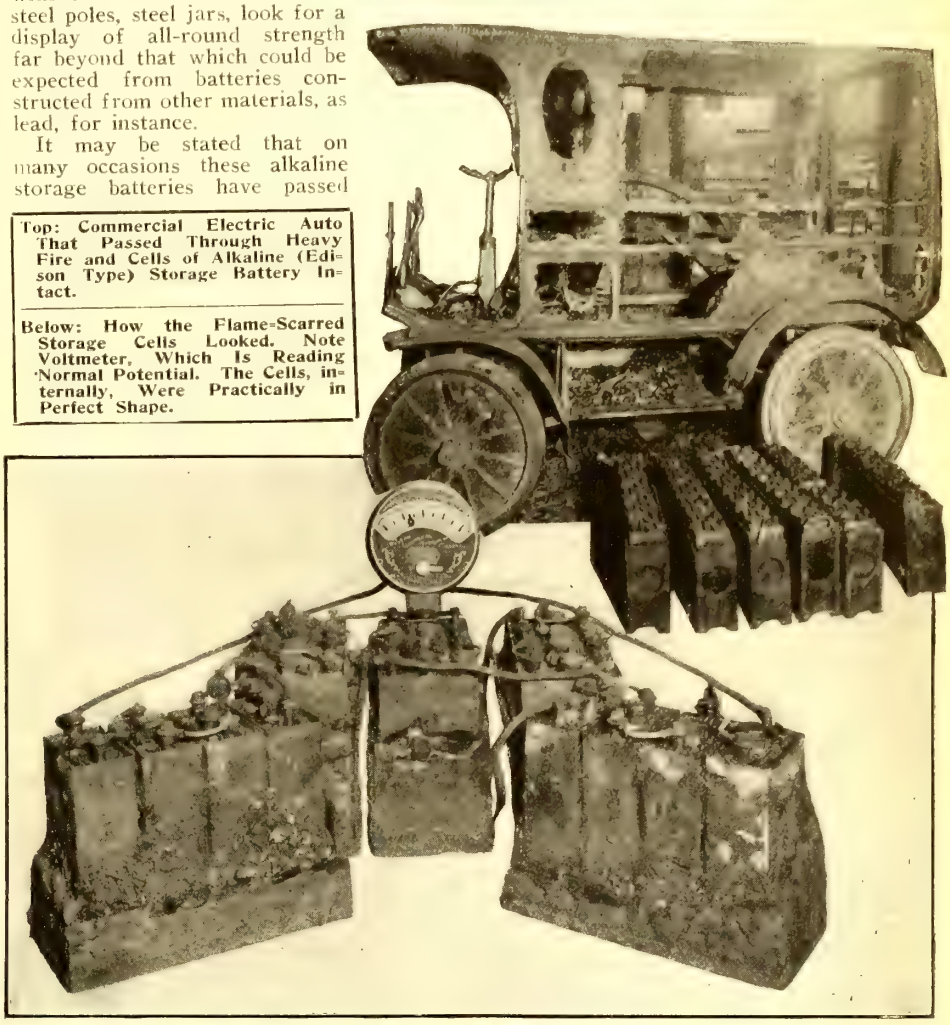
Above: Compact Mercury Arc Rectifier Charging Ignition Batteries, etc. Below: Appearance of Arc Bulb and Reactance With Cover Removed.

binding posts, distinctly marked plus (+) and minus (—), to the corresponding terminals of the storage battery to be charged.

After the alternating-current supply has been turned on by the socket switch the rectifier is tipped slightly by means of the handle on the top. The mercury "arc" will then start, alternating current will be converted into direct current, the battery will begin charging and the apparatus requires no further attention until the battery is entirely charged.

The cost of charging either a 12-volt (six cell) or two 6-volt (two three-cell) batteries for a 10-hour charge is about 13 cents, or the same for a single 6-volt battery. This cost is based on a rate of 10 cents per kilowatt-hour for current. Where the rate is less, the charging cost will naturally be proportionately lower. This cost is exceptionally small when compared with the usual cost of at least 50 cents for charging a 6-volt battery and 75 cents for a 12-volt battery, and there is the added convenience of being able to charge on the ground. This rectifier should thus become very popular with public and private garages where only a few batteries are to be charged.

Automobile Storage Batteries Withstand Fire



By Frank C. Perkins

THE accompanying illustrations show the result of a severe test of an automobile storage battery under most abnormal conditions, and proves that Edison storage batteries are most rugged. Those who use them and are acquainted with their steel construction, steel plates, steel poles, steel jars, look for a display of all-round strength far beyond that which could be expected from batteries constructed from other materials, as lead, for instance.

It may be stated that on many occasions these alkaline storage batteries have passed through fires that have completely burned the wooden trays in which they were assembled, and which have even melted some of the hard rubber insulation. Capacity for such abuse has never been chronicled in storage battery history until the advent of this cell. Many of these experiences have resulted in only a temporary decrease in efficiency instead of complete annihilation, and after making a few necessary repairs the battery has been returned to work better than new. One instance of this was a fire in Indianapolis, a short time ago, that burned a garage to the ground. The next morning the "electric" was run from the ruins on power supplied from its batteries, even though the body of the car was burned and the wooden trays in which the cells were assembled were badly charred.

When the garage of the Electric Light Co. of Cambridge, Mass., was burned and its contents practically destroyed, the remains of one alkaline battery-equipped truck were still serviceable and, with the exception of two cells in this Edison battery, none were beyond repair; in fact, practically nothing had to be done except insert new rubber parts when the cells were recanned.

It is said that all of the bushings and hard rubber insulators of the battery were totally destroyed. However, the connectors had not become loose and there was sufficient charred insulation in place to permit a test. Twenty of these cells when so tested showed an average of 1.3 volts, and the current available in the battery was sufficient to turn a No. 14 wire red hot in a few seconds.

Below: How the Flame-Scarred Storage Cells Looked. Note Voltmeter, Which Is Reading Normal Potential. The Cells, internally, Were Practically in Perfect Shape.

A Telephotograph in the "Movies"

The wide-awake spirit permeating the motion picture of to-day is strongly exemplified in one of the late Pathé films illustrating the episode, "The Disappearing Helmets," from the story of the "Romance of Elaine." The photograph reproduced herewith shows one of the leading characters in this extremely interesting film story, known as Prof. Arnold.

Exciting Movie Scene in Pathe Film, When Prof. Arnold Makes Use of the "Telephotograph."

He is here observed making good use of one of the latest developments of science, or the "Telephotograph," the machine that transmits and reproduces a photograph over a wire.

The film views showing this apparatus in operation are particularly well arranged, especially with respect to the color scheme in the original reproduction.

The photographs transmitted and reproduced over the telephotographic apparatus are, as is generally known, made up of a series of parallel lines closely spaced, and these lines, by their variation in thickness, etc., enable the reproduction of a built-up sketch of photograph. It is now possible to do this work in the laboratory (Dr. Korn's method); but as yet practically no commercial applications have been made, at least in this country, of this remarkable scientific achievement.

Photographs were transmitted over a wire circuit 500 miles in length, between Monaco, Italy, and Paris, France, for use in a Paris daily newspaper several years ago, utilizing Dr. Korn's system.

UNCLE SAM SILENCES TWO AMATEUR WIRELESS PLANTS.

Amateur wireless telegraph operators in the Great Lakes district have been under secret surveillance by officials of the United States Government.

Two licenses have been suspended, nominally because the equipment exceeded in power and sending capacity that permitted by Federal statutes.

One of these suspended stations was in Wilmette, within easy range of the big Government towers at the Great Lakes Naval Training Station, to which are sent many secret dispatches governing army and naval affairs.

No confirmation could be obtained from the Federal radio inspector's office as to whether this activity followed the persistent reports along the north shore than Government officials were investigating persons suspected of being spies for foreign governments.

It was declared that the instrument used by Charles A. Burgy, Jr., in Wilmette had a working radius of 75 miles and used a wave more than 340 meters in length, whereas the greatest permitted to amateurs is 200 meters.

The license of John D. Speicher, 4155 Grand boulevard, was revoked because his instrument also exceeded the limit.

"If these amateur instruments are allowed to operate without restriction," said Charles Blankenship, the Chicago radio inspector, "they will grow to a point where they might interfere seriously with Government regulation.

"Also, suppose a ship on the lake got into trouble and started an 'S-O-S' call for help. Then let one of these powerful instruments try to send at the same time. The usefulness of the ship's instrument might be available for only a few minutes, and disaster follow.

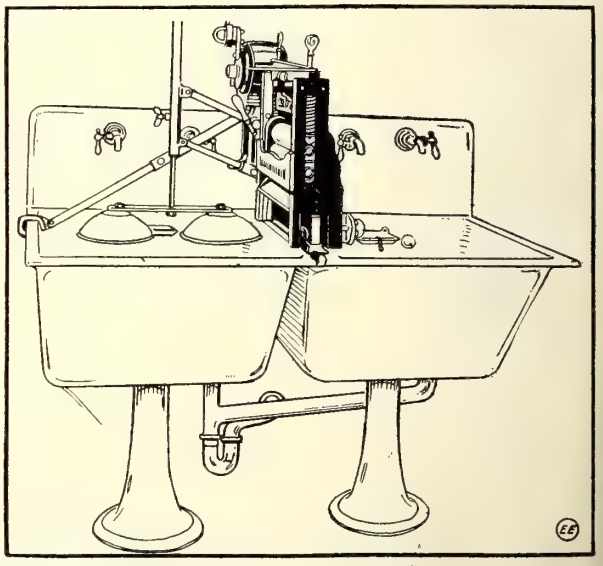
"We have checked up on many of these instruments. We will get after the others at once. Amateurs should understand that it is a dangerous proceeding to violate the statutes."

Especial attention is to be paid the operators who complete their message by any of these signs:

9 CT	9 YH	9 KS
9 OW	9 JP	LW

Complaints have been made that all of them exceed Federal regulations. Several other operators, unlicensed, whose messages have been caught and reported, are being searched for.

SOMETHING NEW IN ELECTRIC WASHERS.



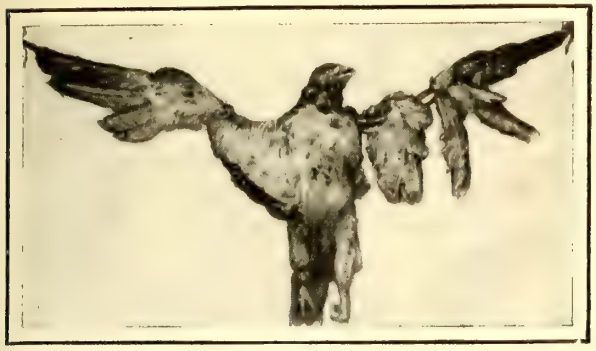
By Frank C. Perkins.

The accompanying drawing shows an effective electric washing machine embodying many new and radically different features, developed at Los Angeles, Cal. This machine washes, wrings, rinses and blues in any stationary tub and eliminates all handling of water by the operator—the plumbing fills and empties the tub for her. Being mounted on the stationary tub, the machine is entirely out of the way; yet it is always ready for use, and avoids all "getting ready" and "putting away."

It is of interest to note that the well-known vacuum principle of washing is utilized. The smooth vacuum cups wash clean, clear through, without injury to the fabric, and anything from the most delicate and sheerest laces to rag-rugs, heavy bedding or blankets can be washed without tearing. The operation is extremely simple. One operating handle, by a slight movement one way or the other, governs the action of the wringer or washer.

To reverse the wringer the electric motor is reversed by means of an ingenious four-point attachment plug. This reversing it electrically instead of mechanically eliminates the complicated gearing otherwise required. Safety of operation is provided for by enclosing the mechanism; by a safety pressure release on the wringer, whereby pressure can be instantly removed from the wringer rolls, and by the four-point attachment plug, which may be quickly detached, stopping the washer or wringer immediately.

This electric washer has a worm-and-gear mechanism, running in ball bearings, with ample lubrication, which reduces friction and wear to a minimum. By loosening a thumbscrew the motor may be removed for other purposes. Simple accessories facilitate its use as a sewing-machine motor, or to operate small grinding or buffing wheels and save the cost of the additional motor usually required with such apparatus.



Ingenious Electrical Washer and Wringer, With Detachable Motor. The Outfit Fits Any Tub.

WIRELESS PLANT AT COOS BAY, ORE., ASSURED.

The removal of the Government wireless station at Cape Blanco to Coal Bank Inlet, near the entrance to Coos Bay, has been assured with the announcement that a five-acre site had been purchased by the Marshfield (Ore.) Chamber of Commerce. The site will be deeded to the Government.

HAWK GROUNDS ELECTRICAL TRANSMISSION LINE.

The illustration herewith shows the remains of a common hawk which some time ago flew into eternity through the transmission lines of the Public Light & Power Co., of Chattanooga, Tenn., near the lock and dam on the Tennessee River. During a storm in the valley of the Tennessee River the hawk, which measures five feet from tip to tip of his wings, either flew into the circuit or, alighting on one phase, stretched his wings, making contact with one phase and the ground wire, which is three feet from the nearest phase.

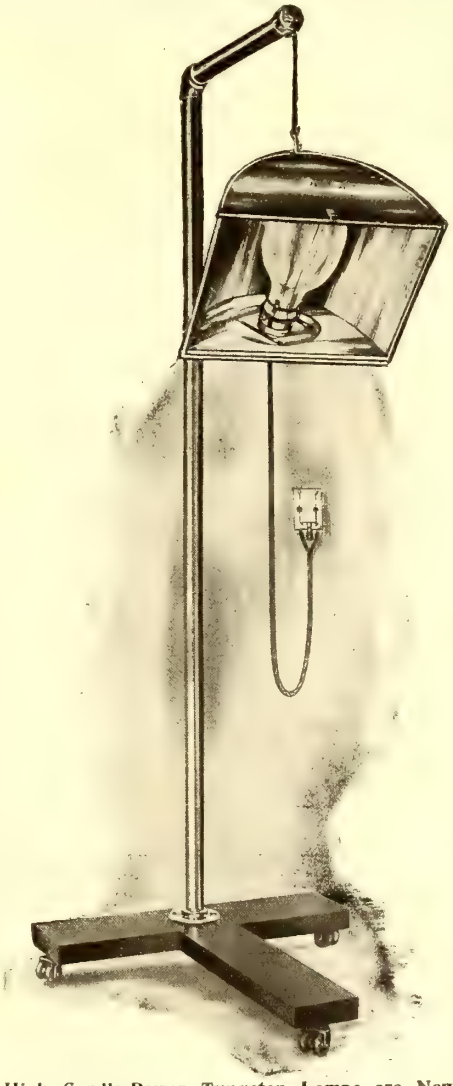
Hawk That Grounded High Tension Wires Besides Causing Its Death.

The line in question operates at 44000 volts, and it cost the company approximately $15 to remedy the trouble after it was located. Occurrences of this kind, while common in some sections of the country, are rather rare in the Tennessee River valley, but no matter where they occur they are beyond the control of transmission companies, a fact oftentimes lost sight of by the general public, which may be temporarily inconvenienced because of the failure of a transmission circuit from such cause. Some years ago a similar case occurred on a Western high-tension transmission line, in which a bobcat played the leading rôle. Being chased the animal took refuge in the high voltage line and, needless to say, he got the surprise of his life. One blinding flash announced the grand finale of his existence.

NEW RADIO SECRECY SCHEME TRIED BY U. S. NAVY.

Sending of radiograms by vessels at sea without revealing even the approximate location of the ship dispatching the message —a problem which has confronted naval strategists since the discovery of wireless communcation—virtually has been accomplished. Experiments of that order made by the "enemy" divisions of the Atlantic fleet during the recent war game were said by naval officials recently to have been highly satisfactory.

During the time the two forces were engaged in the maneuvers, one moving to attack the coast and the other to defend it, the vessels were in constant communication with the navy yards and supply stations ashore, but neither force was able to determine the location of the other by the use of the wireless.



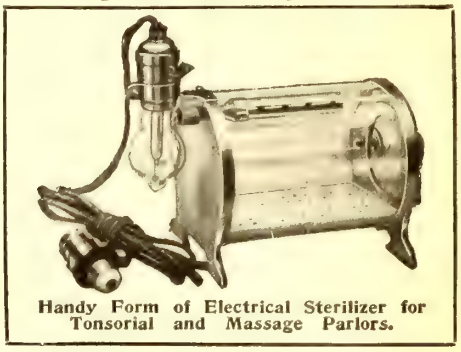
The messages were disguised by means known only to the Navy Department, and, for the first time in the history of the war game maneuvers they gave the vessels intercepting them no indication as to where they came from or what force of wave length had been used in transmission.

Ordinarily, naval officers say, an experienced operator can estimate the location or proximity of a vessel by listening in or receiving messages it is sending.

LARGE TUNGSTEN LAMPS USED FOR ELECTRO-MEDICAL TREATMENT.

The illustration presented herewith shows the arrangement of a large-size electro-therapeutical treatment lamp comprising a high candlepower tungsten lamp, which consumes from 500 to 1,000 watts. The lamp comes mounted in a suitable reflector. A flexible cord and plug connection is supplied with the lamp for insertion in a wall pocket. The reflector and lamp may be moved up or down to any required height by a specially arranged balancing scheme, the weight for which slides within the hollow upright standard, which is in turn mounted on a substantial pedestal. The pedestal is suitably mounted on casters so as to permit moving the treatment lamp about as required.

It has lately been found that treatment by the rays given forth by such a high candlepower lamp is of great value for certain diseases and ailments, and this form of treatment is being extended more and more every day as its efficacious properties become more widely known to the medical profession.



High Candle-Power Tungsten Lamps are Now Widely Used for Heat and Ultra-Violet Ray Treatment by Physicians. Adjusts to Any Position.

Their effects are not unlike the effects from sunbaths, in fact they really take the place of the sun for all practical purposes in the treatment of skin diseases.

ELECTRIC STERILIZER SOLVES MANY PROBLEMS.

A new electric sterilizer has been recently put on the market by a New York concern. This new sterilizer is herewith shown and consists of a gas-tight cylinder made of glass. A door is provided on one end, as perceived, and is supplied with a rubber gasket for making it absolutely air-tight when it is closed.

Handy Form of Electrical Sterilizer for Tonsorial and Massage Parlors.

The vaporizer, which is enclosed in the glass chamber, as seen on the upper left hand corner of the apparatus, consists of a glass bulb made similarly to an incandescent electric lamp, but it contains two wires, which are not connected to each other and thereby form two entirely distinct electrodes. These are immersed in a liquid which forms the electrolyte between the two electrodes.

A small hole is provided on one side of this bulb, into which the liquid is poured and whereby the gas escapes when the electrolyte is decomposed by the electric current. The liquid used in this vaporizer is so made that when it is decomposed it liberates a gas which is highly germicidal and consequently kills any germs that it attacks. The apparatus is a complete unit by itself and can be readily removed by unscrewing it from the screw socket as depicted.

This electro-formalin sterilizer is very efficient and it will undoubtedly find its way into hospitals and especially into dental laboratories, where surgical instruments are in constant use. It can also be used in the home for sterilizing rubber goods, such as babies' nipples, etc., and other various things which need constant sterilizing.

HAWKEYE RADIO ASSOCIATION OF LAMONI, IOWA.

The Hawkeye Radio Association held its annual convention on Sept. 1 and 2 at Engineering Hall, Iowa State College, at Ames. Officers for the year 1915-1916 were elected as follows: President, Ralph Batcher; secretary, Arthur B. Church; treasurer, Hollis Sels. After the general business was finished several talks were given by the new officers and club members, in which some very interesting suggestions were offered. A large assortment of apparatus from various companies was on display and tried out, several new instruments giving remarkable results, especially the new amplifying receivers but recently placed on the market. The convention adjourned with its members feeling highly satisfied with the good time they had had and the large amount of information collected. All wireless operators in Iowa should not fail to join this association, as the use of the club's testing instruments alone is worth more than the entrance fee. Communication with similar organizations is invited. Address the Secretary, Arthur B. Church, Lamoni, Iowa.

The housewife would appreciate an electric iron more than the vote. Take a hint Mr. Man.

The Shirikari Tentacle

By George Frederic Stratton

TWENTY-FOUR hours after the marvelous Poniatowski Ray had put the Japo-Chinese fleet in Cisneros Bay out of commission, Cawthorne, the young millionaire who had backed the inventor with both money and enthusiasm, was on a special train going north. With him was Kilroth, his mechanician, and between the only passenger coach and the locomotive was a box car containing two of the Poniatowski projectors which they were taking to install on one of Admiral Sorensby's vessels in San Diego Bay.

They had crossed the Arizona border at Nogales and there saw the first American newspaper they had seen since they had operated the new Gravitation Nullifiers on the Mexican side of the Rio Grande. And what they now read was as amazingly startling as any of their own exploits had been.

ADMIRAL SORENSBY'S FLEET ATTACKED BY SOME MYSTERIOUS AND UNSEEN FOE

Submarines Crippled and Battleships Thrown Into Confusion.

CONSTERNATION IN WASHINGTON

(*Special to The Nogales Star.*)

WASHINGTON, Aug. 10.—Information has just been wired to the Secretary of the Navy that during the last twenty-four hours three submarines cruising in San Diego Bay have come to the surface and displayed distress signals. Upon help reaching them it was reported that the boats and equipment had suddenly become charged with an electric current so powerful as to cause severe shocks to the crew when they came in contact with any metal. Two of the men on the S-3 were killed outright. On all three boats this astounding attack of uncontrolled electricity burned out the motor armatures, disabling the boats.

The battleship Idaho felt the same mysterious influence. For fifteen minutes she was practically out of control, because of the helplessness of the crew. Her wireless antenna and equipment was instantly burned out. Then the shock left as suddenly as it had occurred.

The weather was perfectly clear, no atmospheric disturbance being evident, and it seems impossible that any action by the enemy could have caused the trouble, as although the reserve Japo-Chinese fleet is on its way across the Pacific it is known by scout-aeros that it is over a thousand miles away. There is not a submarine in the Bay except those under Admiral Sorensby's command, and no aeroplanes have been seen for ten days.

Ned Cawthorne read the account a second time and then muttered to Kilroth: "What do you make of it, Billy?"

The inventor-machinist had no answer ready. His eyes dwindled to pin-points and peered vacantly at the big mogul which was backing down to couple onto their cars. After a pause he shook his head and grunted:

"It's beyond me, Cawthorne. Looks as if they'd been connected up to some very high-voltage current—but, how? No attempt to send a high-power current by wireless has yet succeeded."

"Humph! How about that Hammond torpedo boat? That's been doing wonderful work under wireless control, Kilroth. And the Japs tried, before the war, to buy all information and plans."

"It's wireless control only, Cawthorne. It carries its own power with it and, more than that, it's not a submarine. It operates in plain sight. Nothing of that type can be in San Diego Bay. There's some new scheme afoot, or afloat; but I haven't the faintest glimmer of an idea what it can be!"

* * * * * * * *

When they reached the Bay they found that the consternation had increased tremendously. A large number of the forty submarines were tied up with burnt-out motors; among them were six of the Cawthorne Omegon vapor boats which had so successfully attacked the enemy's dreadnoughts outside San Francisco.

Cawthorne and Kilroth were ordered to the flagship to consult with the Admiral on the disposition of the Poniatowski tubes, and while on board they had a full demonstration of the mysterious current. They were in the Admiral's cabin when a report came over the bridge telephone:

"Admiral! The ship is electrified. The men are——" Then with a crash in the receiver the communication stopped.

They rushed out to the main deck and saw officers and crew carefully avoiding any contact of their hands with any metal. Cawthorne placed his hand on a steel guy as he hurriedly passed it and instantly fell to the deck severely shocked. The vessel was at anchor and in smooth water, so that no orders for immediate operation were necessary.

Round the side of the turrets laid five deck hands dead. They had been swabbing down the deck and were in bare feet, which exposed them to the full force of the mysterious current when they had come in contact with the turret. Cawthorne had regained his feet, assisted by one of the officers, and, shaking in every fiber, glanced about him. Men were crouching strictly aloof from any article except the deck on which they were standing, and evidently too terrified to make any movement. The Admiral stood grasping the hempen falls of a boat tackle and listening to the report of the deck officer.

"The conditions are exactly the same, sir, as have been reported from other ships. It is impossible to handle any equipment of metal. In the engine room the stokers are crouched on the coal. It would take a winch and tackle to draw them off that."

The bewilderment, indignation and disgust on the Admiral's face were supreme. "Signal the *Minnesota* to send her diving crew and outfit over here at once! Let their launch lay away from the ship and the diver search below and around for any indication of concealed wires or torpedoes!"

The officer hesitated. "Our wireless is destroyed, Admiral! We shall have to use flag signals."

"Do so, sir. Stay! Is it possible to operate that starboard launch?"

The officer cautiously looked over the rail at the launch moored at the end of the boat-boom and hailed a man aboard her:

"Below there! Are you feeling any of the current among your machinery?"

"No, sir. None at all."

Lieutenant Barlow turned to the Admiral. "She can be sent away, sir, if we can get a crew aboard. But no man can reach her by the ladder."

"Hoist a man over the rail by a tackle!" commanded Sorensby. "Drop him in the water and he'll probably be safe from the current and can reach the launch. Two men can handle her."

This was gingerly and very deliberately done and in a few minutes the launch motor was started and the boat darted away to the *Minnesota* with the Admiral's order.

But before she had covered half the distance the strange electric current left the ship. In a moment everything was in its normal condition and, responding to a sharp order, deck hands were carrying the dead men below. Then again came the shock, tumbling men to the decks—some never to rise again. This time the Admiral, ascending the ladder to the bridge, was plunged down severely bruised and shaken.

The second attack lasted less than a minute, but the demoralization it caused was complete. Had one of the enemy's vessels appeared at that minute—even an unarmored collier—no offensive action could have been taken against her. Not a single gun could have been operated or fired.

* * * * * * * *

Two of the speediest light cruisers were to receive and operate the Poniatowski ray projectors, and on the day following the attack on the flagship Cawthorne and Kilroth had superintended the loading of the tubes onto a barge. As they steamed out to the cruisers they gazed at the group of great dreadnoughts lying at various anchorages, faint streams of smoke lazily curling from the funnels.

"There's a vessel apparently aground over there!" exclaimed Kilroth. "I noticed her yesterday. She's not one of the fleet, I guess. Looks like a tramp freighter."

"That's what she is, sir!" exclaimed one of the barge hands. "The *Aratusa*, from Manila to San Francisco. She went aground on the Chulavis Bar a week ago with a cargo of sugar. They say she's waiting for lighters."

They ran alongside the cruiser *Trenton* and hoisting tackle was rigged to transfer the big twenty-four-foot ray tube. It was hoisted above the deck and the hands were swinging the derrick around previous to lowering when the appalling current again attacked the vessel. Ropes were dropped as men recoiled in horror. At the winch the attendant at the gear clutch shrieked as he dropped away from the lever, and the winch, still operating without control, ran the great aluminum tube up against the

IN this remarkable story Mr. Stratton shows how a Dreadnought is put out of action by means of a certain electric current directed to the ship by an enemy. If this story does not sound plausible to you, because of the feature where the electric current is sent to the metallic hull of the ship, which would apparently short-circuit with the ocean, kindly consider this: The body of an electric eel is a first class conductor, so is the water in which the fish lives. Nevertheless the fish without killing itself, can kill a horse, if it touches the latter in a vital spot. Although the fish, the water and the horse are "short-circuited," the current sent from the fish is able to kill the horse, without harming itself. Our most able electricians have as yet not solved this apparent paradox.

collar of the derrick boom. Kilroth saw what would happen and sprang to the clutch lever, but was thrown as he grasped it, and the next instant a ripping, tearing crash accompanied the smashing away of the collar and the ray tube slipped down

But on the barge one discovery had been made. Jake O'Shea, a deck hand, who had jumped from the cruiser, had gone deeper than he expected and as he came up and swam to the barge a fine wire was twisted around him. It was about fifty feet long

treatment he had once revived for a few moments and gasped: *"The Tentacle! The electric Tentacle!"* and had then again lost consciousness. Whether he really knew anything of such a contrivance or had become obsessed or perhaps insane over the

" * * * Tiny Submarines * * * They Run Out with a Fine Composite Wire Cable, Through Which They Are Directed and Through Which That Current Is Shot After They Fasten Onto Their Prey * * * "

onto the ship's rail and from there into the water, instantly going to the bottom.

The *Trenton* sustained the longest attack of any vessel of the fleet up to that time. When the current went off she was practically out of commission. Except that her wireless equipment and all her motors were burned out, she had sustained no damage, but her crew was uncontrollably frantic. The cap of the rail was of wood and half of the men had vaulted over that into the ocean and swam to the barge, which had cast off her lines and drifted away. Of the other half several had been killed outright; others were so severely shocked as to be almost incapable of action or reason.

Flag signals reported the calamity to the Admiral, who signaled back: "Send the barge ashore immediately with orders to unload the other projector and store it in safety!"

Cawthorne breathed a great sigh of relief as he heard that order. Although he growled to Kilroth: "This is the first time that one of our devices has had to beat a retreat!" he cheerily said to the Captain:

"That tube will operate just as effectively from the land as from a vessel. She'll project that ray for twenty miles and that'll catch any enemy that comes into the bay."

"What if that unknown electric current should get into operation on shore?" retorted the Captain.

Cawthorne winced. Not one guess—not a particle of theory had any of the officers or engineers of the fleet expressed as to that mysterious and appalling agent and, knowing nothing of its origin, no idea of its limit could be evolved.

and at twelve-foot intervals were small hollow balls—evidently of aluminum.

They shouted back to the cruiser of their discovery and the launch took Cawthorne, Kilroth and a lieutenant to the barge with orders to secure that wire and take it to the flagship. It was very fine and of some composite metal which neither of the men could designate.

Kilroth, who had closely examined the two ends, exclaimed:

"One end has been broken—torn apart. See this!" and he held up the wire showing the end raveled out, more like a piece of fibrous cloth than like metal. The other end showed distinctly the clean, incisive mark of keen clippers.

But it showed nothing clearly to the engineers and naval officers who were brought over to the flagship from every battleship in the bay. They decided that the aluminum balls were floats to hold that wire—as they found by tests—thirty or forty feet below the surface.

BARON MÜNCHHAUSEN,

as will be noted, has failed to make his appearance this month. Urgent Wireless Telegrams to his chronologist-in-chief, the Hon. I. M. Alier, of Yankton, Mass., disclosed the fact that the venerable old gentleman has contracted a virulent case of *Atmospheris Marsianis*, which sometimes attacks Interplanetarian travelers not acclimatized to the peculiar Martian air. Mr. Alier, however, states that Professor Flitternix, the Baron's companion, advises him that Münchhausen will be back on the job next month. Of course we're sorry, but what can one do?

That night word was sent to the Admiral from a San Diego hospital that a man had been picked up on the south shore totally unconscious; that under medical

accounts of the mysterious current the physicians could not say.

* * * * * * * *

It was three days after that word was received that the man was awake and rational, and frantically eager to make something known to some officer of the navy. Cawthorne was invited to accompany the Admiral and two officers, and although the poor wretch on the cot was emaciated and showed evidences of a fearful struggle, both of mind and body, he slowly told his story. Eliminating his frequent pitiful demonstrations of terror or remorse and his occasional lapses into semi-unconsciousness, he revealed the following:

"My name is Forsythe—Lester Forsythe. Two years ago I invented a device something after the manner of a submarine torpedo, only it wasn't designed for explosives—only to transmit an electric current. I offered it to the United States men at a moderate price after they had made a full examination and tests, but they couldn't make any such contract with me. All they could do was to look into the thing thoroughly and then, if they liked it, recommend Congress to purchase. That was too indefinite to suit me and as the Japs got after me and made big offers I took it up with them. That was before there was the least indication of war.

"I went over to Japan and looked after the development and construction of a lot of those contrivances—we got to calling them 'Shirikari Tentacles.' Say those Japs can teach something about secrecy, all right. There wasn't a workman in those shops who ever got outside, or sent a letter

The Marvels of Modern Physics

By Rogers D. Rusk

Assistant Instructor in Physics, Ohio Wesleyan University.

THE scientist who would communicate across space with our sister planets, or who would harness the sun directly, or who would do any other of the seeming impossibilities, has always been disbelieved, if not openly ridiculed. However, the change in attitude which has come over the world in a few short centuries is very striking.

Barely 300 years ago Galileo was twice brought before the court for daring to assert his theory of the rotation of the earth and was made to publicly retract his statement. He was heard to murmur afterward, though, "It does move, for all of that."

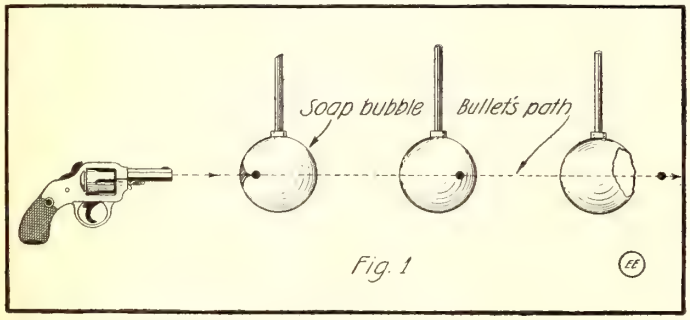

Fig. 1. Diagram Illustrating How a Soap Bubble Fails to Break Until a Bullet Fired Through Same Leaves the Bubble.

A hundred years ago, in our own land, a curious, skeptical crowd of people gathered on the banks of the Hudson River to see what would happen to the "crazy" man who thought he had invented a boat to run by steam. Robert Fulton's steamboat ran, however, "for all of that."

Thus it has always been. Science, besides her own battles, has had to combat the skepticism of the times, and only now is she coming into her rightful honors.

It is hard to measure just how great the accomplishments of the past few years are, for it takes ages to bring out the true worth of a discovery. We can gain an idea of the wonderful advance of the past century, however, by imagining one of the scientists of a hundred years ago brought back for a time to the busy world of to-day. Why, the very commonplace things of our life would amaze him. We can almost see him rubbing his eyes, his brain in a whirl, and at last in despair giving up trying to understand. The remarkable progress of the world would be very vivid to his eyes, while to our own it is hardly noticeable.

For this reason it is the purpose of this article (1) to emphasize some of the greater physical achievements of recent years and (2) to describe in some detail a few of the marvels of experimental physics which to the unscientific mind seem truly like absolute impossibilities.

The majority of recent inventions fall well within the domain of applied physics. Man's victory over the air with heavier-than-air machines and the invention of wireless telegraphy are too well known to need emphasis.

Modern artillery, the seagoing submarine, the phonograph and the automobile, different as they are, are only advanced applications of important basic physical principles.

The field of modern physics has so broadened that it now touches in some way practically every material phase of human endeavor. This rapidly widening field and the constant stream of new discoveries and inventions serve to increase man's control over nature and decrease his physical limitations.

The X-ray has marvelously decreased the limitations of our vision, for we can now "look through" space and objects and even into the human body.

The spectroscope has enabled us to look even to the stars themselves and tell their composition.

Electricity has enabled us to turn night into day and has permitted us to send energy over a thin metallic wire that would create thousands of horsepower.

Modern photography has enabled us to picture the bullet in its flight (see Fig. 1), and even sound waves in the air, while the wireless telephone, like the magic carpet of Bagdad of old, has practically annihilated space. The fairy tales of the ancients are indeed coming true, it seems.

All of the above facts are public property. Nearly every person has heard of them and knows something about them. Few people, however, ever stop to think that these were not the products of a moment's labor or chance discovery. In reality it has taken many years of painstaking labor on the principles involved to make them possible.

The results achieved in the field of pure physical research by those who are pushing forward the boundaries of science are often more marvelous than those results better known to the world.

In later articles the writer may take up the problems which modern physicists are attacking and the results so far achieved, but on account of space limitations this is impossible at present.

Physical research of late years has been most successful in the realms of electricity and radiation. Because these results, in a marvelous manner, have gone a long way toward answering some of the great questions of science, examples of the results obtained will be confined to these fields alone.

Fifty years ago scientists knew that matter could be divided into particles called *molecules,* but to this day the molecule itself has not been seen, for it would take, on an average, about 1,000 molecules, side by side, to make a speck visible with the strongest microscope. However, we know perfectly well that the molecule really exists. Our best proofs come from experimentation with gases and it has lately been proved that the so-called *Brownian movements* are caused by them. Brownian movements have been known for some time as the movements of a globule of liquid (generally oil) suspended in air, or some gases in which there are absolutely no currents. Notwithstanding the fact that the gas may be perfectly stagnant, the globules will dance around at a merry rate due to their bombardment by the flying molecules.

So much for the molecule, but that does not help us very much with reference to the *atom.* Still more impossible to see, how are we to know that it exists? It is a well-known fact that the molecule of any chemical compound can be separated into its constituent parts, and these smallest divisible parts of the elements themselves we term atoms. Practically the same proofs of their physical existence apply to molecules, but the theory that these are the smallest possible divisions of matter is everlastingly exploded by the electron theory. This theory asserts that the atom is composed of a positively charged nuclear mass, about which revolves, at relatively large distances, elemental particles or negative electric charges—the *electrons.*

Truly, here we have an advance into the universe of the minute as remarkable and as wonderful as any journey might be among the bodies of our heavenly universe.

As we have never seen the molecule or atom, it might seem a greater impossibility to prove the existence of the electron.

One of the most brilliant experiments of all science, however, was performed by Prof. Milliken, of Chicago University, when he actually caught and measured the electron. His method was simple enough to admit of explanation here, and all the more valuable on account of its simplicity, as the amount of error in the experiment was thus diminished.

An ordinary atomizer (A) was connected with a reservoir (R), as in Fig. 2, and globules of oil were forced into R from the atomizer by a stream of air passing through glass wool in the tube T, which caught the dust present in the air.

A single droplet of oil was then allowed to drop through a pinhole (P) between two metal plates M and N. As the drop fell it was observed through a magnifying telescope, and an electric field was created between M and N by connecting these plates to a source of current. The speed of the falling droplet of oil could now be increased or diminished, depending on the direction of the field, because the droplet itself carried a slight charge resulting from friction. By adjusting the field the droplet could be made to move at will between the plates M and N. In time the droplet would meet and catch upon its surface an *ion* from the air—an ion, of course, being the carrier of an electric charge.

The sign and size of the ionic charge could be measured by its effect on the speed of the droplet, and if the sign was found negative it was then due to the *electron,* which is always considered negative. Thus did Prof. Milliken capture and measure the electron, but many careful adjustments and methods of precision were necessary, in addition, to bring about the best results. That the size of the electron was determined as one twelve-hundredth that of a hydrogen atom is proof in itself of the brilliancy of the experiment.

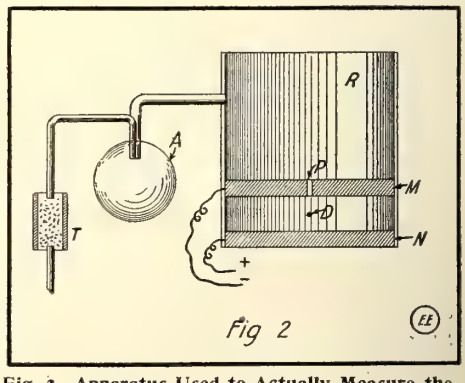

Fig. 2. Apparatus Used to Actually Measure the Electron, by Prof. Milliken.

Rutherford's work on the positive particle is equally famous. In his well-known "Counting Experiment" he determined the charge of a positive particle by counting

RADIO DEPARTMENT

Latest De Forest Radio Apparatus

DR. DE FOREST and his associates have been recently developing several new radio apparata which we herewith illustrate. Fig. 1 depicts his latest portable wireless telegraphic and telephonic transmitter, as well as receiving outfit. This machine is of the "arc" type and operates on 600 volts direct current. The arc is specially constructed, consisting of two platinum alloy electrodes, which are cooled by means of radiating vanes surrounding them. This self-starting arc is enclosed in the case. The oscillating circuit consists of a variable capacity shown on the left of the case, a variable inductance seen in the center foreground of the cabinet and a hot wire ammeter, shown in the center background, which latter is used for indicating the amount of current transmitted to the antenna. The current in the circuit is varied by the voice through the medium of two specially designed microphones interlocked in parallel with a single mouthpiece connected to both as perceived in the illustration. This set can also be used for telegraphic transmission by substituting the regular telegraph key for the microphone. This is done by merely changing the position of a 2-point switch, which is located on the left of the transmitter bracket base, the key being placed on the cover of the cabinet as depicted in the illustration.

The receiver consists of the standard "audion" detector, variable inductances and capacity and a pair of 'phones. The receiving cabinet is shown on the lower left part of the illustration. This outfit is very compact and portable, which makes it the ideal set for scouting work.

One of the latest audion and ultra-audion receiving sets which is capable of receiving both undamped and damped wave stations is shown in Fig. 4. This consists of an ultra-audion tube, as perceived, with its grid and wing connected properly to an inductance and variable capacity. This is done for the purpose of making the audion oscillate in order to produce "beats," which is essential, of course, for the reception of signals transmitted by stations employing the arc or high frequency alternator. The oscillations produced by the audion are regulated by means of a bridge condenser placed on the lower center part of the cabinet as perceived. An ammeter is used for indicating the amount of current the bulb filament is consuming. The high voltage current in the tube is supplied by a dynamo of from 80 to 125 volt capacity, being regulated by means of a potentiometer which is seen in the extreme upper corner of the illustration. With the potentiometer method of regulating the high voltage a finer adjustment than with batteries can be obtained, as small increments of voltages can be made by merely changing the position of the runner of the regulating instrument. This also eliminates the troublesome batteries, which were, until the present, always used on high-grade audion receiving outfits. A switch for changing from *arc* to *spark* receiving is provided and is seen at the lower right corner of the cabinet. This set is exclusively used by the United States navy on its battleships.

An audion cabinet set for the amateur is also one of the latest products of the De Forest laboratory. One of these is illustrated in Fig. 3. Its cabinet is modeled similarly to the commercial ones. One feature of this type of audion receptor is that it employs a potentiometer for regulating the high voltage battery in the wing circuit, thus eliminating the unnecessary switch contacts. The old method of regulating the high voltage was not very delicate, as increments of four volts could only be added to the circuit, but with this method infinitesimal increments of voltage can be admitted to the wing circuit. The potentiometer is shown on the upper left corner of the audion and consists of a high resistance semi-circular graphite rod, held in place by means of two substantial brass clips. The switch handle contains a circular graphite button sliding over the rod. The only thing that is necessary is to con-

AMERICAN OPTICAL CO. INSTALLS RADIO TIME SET.

A one-way wireless station, capable only of receiving wireless messages, without any apparatus for sending, has now become popular among industrial concerns, who find the wireless a convenient and accurate means for receiving standard time daily at noon and 10:00 p. m. This economical apparatus, costing but a small amount, consists simply of a receiving panel about 20x16 inches and a suitable aerial. This receiving apparatus is capable under favorable conditions of receiving from a distance of 2,000 miles. Only a short time is required for the operator to learn the standard wireless time code, so as to be able to receive them properly.

The American Optical Company, of Southbridge, Mass., is among the latest to install a radio time receiving apparatus with which it gets standard time from Arlington, Va., daily. The yearly saving and convenience of the wireless message over the telegram has satisfied the officials of this concern that the venture is to be a most satisfactory one. Referring to the group of illustrations the time clocks to be checked by radio twice daily are seen in the upper left view. The antenna is observed at the right, as well as the operator in the act of tuning in the time signals.

Top Left: Radio Time Receiver and Master Clocks at American Optical Co.'s Plant in Southbridge, Mass.

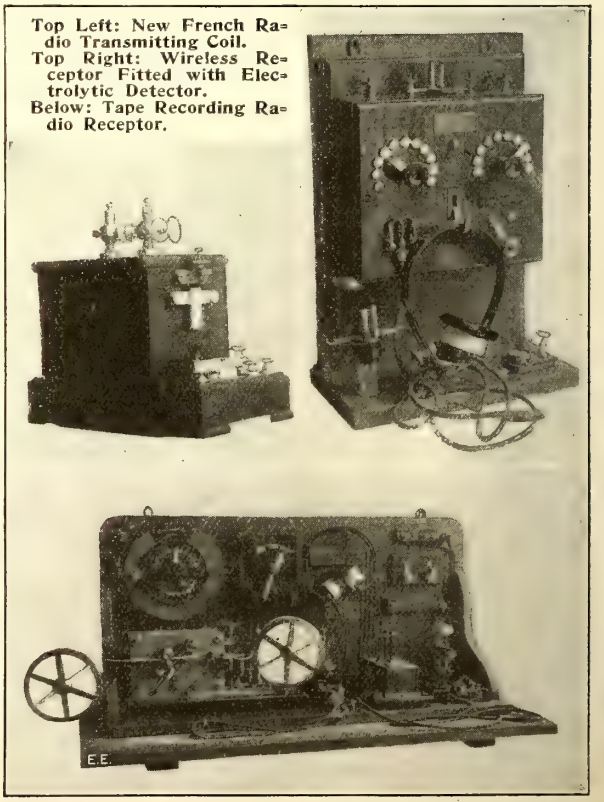
GREAT LAKES SHIPS OPEN WAR ON MARCONI RADIO.

Expressing the intention of putting in $20,000 worth of wireless equipment to free itself from the present wireless control of the Great Lakes service, the Goodrich Transit Co. announced it had closed with Kilbourne & Clark, of Seattle, for independent wireless equipment for the steamship "Nevada," now building at Manitowoc, Wis. The new ice crusher went into service in December.

W. H. Thorp, vice-president and general manager of the Goodrich Co., stated recently:

"The Marconi charges have increased approximately 100 per cent. within a recent period. Their charges have to us become practically prohibitive. The public, both traveling and shipping, has come to demand wireless safety equipment, hence a great increase in the volume of wireless business."

NEW WIRELESS STATION AT CAVITE, MANILA.



Three 600-foot steel towers for wireless stations are to be erected in Cavite in the near future. It is believed that towers of that height, if properly equipped, will be able to receive wireless messages across the Pacific Ocean.

NEW FRENCH RADIO INSTRUMENTS.

Several new French radio apparatus are illustrated herewith. Fig. 1 (upper left) shows an improved spark coil for use in portable wireless transmitting, which is operated on storage batteries. This coil is fitted with an extra heavy Morse key mounted on the base of the coil itself, as perceived. Also the vibrator is of special construction, so as to give a constant interrupter speed, and the contact spring carrying the platinum point is placed at right angles to the armature proper, as may be noted. By this method of construction the contact screw with platinum point is located in a vertical position and is thus more readily adjusted than in the common form of spark coil vibrator. This coil is fitted with a new form of spark gap, known as the "mushroom" gap, taking its name from the fact that the sparking electrodes have the form of a mushroom. The coil here shown is capable of transmitting 25 kilometers and measures 35 cm. long, 19 cm. wide and 28 cm. high. It operates on a four-volt storage battery successfully.

Fig. 2 (upper right) shows a very compact wireless receiving set of the Ducretet type, as supplied with a sealed point electrolytic detector, having a removable electrode, which is observed resting on the base at the left. This apparatus is fitted with an automatic cut-out switch for the battery circuit, on which the head 'phones may be hung when the instrument is not in use. This is a feature which many of the French and other foreign makers have incorporated in their sets, but the American manufacturers of similar machines seem loath, for some reason or other, to adopt. The tuning inductances of this receiving set are adjustable by means of two multi-point switches placed on the front of the cabinet, as illustration indicates. A mineral detector is also supplied with the set and may be seen at the right of the base in the illustration. Either detector may be placed into or out of the circuit, as there are provided slotted contact clips which are clamped under the binding post nuts on the top of the cabinet.

In Fig. 3 (bottom) is depicted a complete wireless receiving outfit capable of making a permanent record on a moving paper strip of the received radio signals. This complete apparatus includes a special rotary tuning coil observed at the upper left portion of the illustration. The equipment also includes head 'phones, which may be used in place of the tape recorder when desired. In conjunction with a sealed point electrolytic detector of very fine construction, there is operated an extremely sensitive polarized relay which in turn controls the tape recorder. When desired the signals may be interpreted by means of an electric bell, which is perceived at the right side of the set. Potentiometers and battery are, of course, incorporated in the make-up of the outfit for properly controlling the electrolytic detector .

The Dubilier Multiple Musical Tone Radio System

RECENT progress in wireless communication has established this branch of science as an indispensable means of transmitting intelligence from one place to another without the use of connecting wires.

A great impetus was given to wireless when the signals transmitted were of a

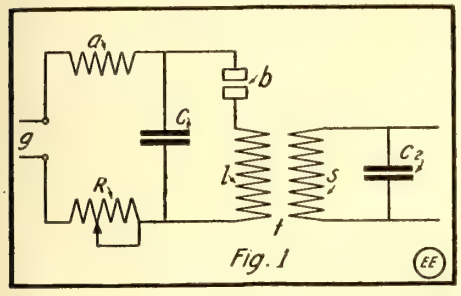

Fig. 1. Circuits of the Dubilier Radio Buzzer Set.

musical tone instead of a mere noise in a telephone receiver. For producing these tones usually an alternator or generator of the rotary type was used, but this becomes a difficult problem, especially for the outputs necessary for portable radio sets. With the elimination of these difficulties in view, but retaining the same desired characteristics, Mr. Dubilier has devised an apparatus by the application of what is known as the Multiple Musical Tone System.

The deserving characteristics of a higher note in the telephone receiver are well known, and is of great importance for the reason that it can easily be distinguished from frequent disturbing noises caused by atmospheric discharges, etc.; it has been proven that these tones carry far better and for longer distance with the minimum amount of energy.

In the present system used the sparks are produced by an alternating dynamo having a corresponding frequency, and as the pitch depends upon the number of cycles of the alternator, a variety of tones is obtained by changing the number of poles or by changing the speed. Both possibilities necessitate and require a complicated construction, combined with low efficiency.

By the system described later on most of the difficulties and defects are avoided; different tones can be produced, one immediately after the other, without any difficulty, and by reason of this a freedom

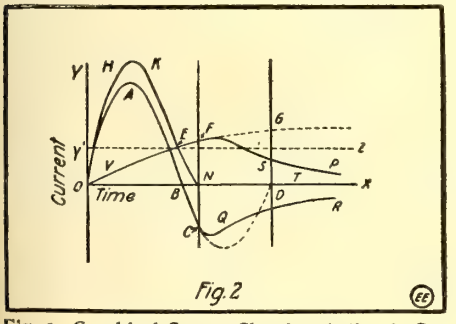

Fig. 2. Graphical Curves Showing Action in Dubilier Radio Transmitter.

from disturbance never attained heretofore is arrived at. Furthermore, for Governmental purposes, a message can be sent in different tones, hence cutting down to a minimum all possibility of interference from the enemy.

If the Morse or any other telegraph alphabet be used, the tone variations can also be employed by using different tones for the dots and dashes, thus preventing messages from being understood by outsiders. Owing to the fact that such a dash does not occupy more time than a dot in transmission, the sending speed of messages is also accelerated.

Due to the peculiar construction of the Dubilier apparatus, the efficiency of same, especially for small equipment, is higher than similar apparatus at present on the market. This is an important feature where a portable field, motor car or aeroplane installation is to be considered, for a maximum amount of power must be obtained with the lightest weight possible and in the smallest space.

In tests made it was found that as much as 50 per cent. of the direct current can be transformed into oscillations, and from this we can safely say it is 100 per cent. higher in efficiency than any other instrument.

In order to obtain the properties and characteristics of the multiple musical tone system, using direct current with an ideal impulse excitation, a connection as shown in Fig. 1 must be used.

In Fig. 1 g is a direct current source, a is an inductive resistance in the form of an electro-magnet for operating the oscillator b. The oscillator circuit c-l-b is tuned to the desired frequency. When resonance is caused to exist between the oscillating circuit and the oscillator there will be a steady and even current produced in the secondary s of the transformer f, which charges the high tension condenser c_2.

On all types of apparatus, using up to 500 watts and a magnetic mechanical oscillator, the electrical frequency of the oscillating circuit will control (to a certain extent) the vibrating frequency of the oscillator, that is to say, it will force the reed to vibrate at a desired frequency so as to keep in step with the circuit.

In Figure 2 the curve OY represents the current amplitude and OX the time axis. For the purpose of illustration, suppose the origin o to correspond with the moment when the condenser c, Fig. 1, is fully charged, and the oscillator b is closed. If the circuit were closed permanently the condenser would discharge through l, as a damped wave, indicated by the curve (Fig. 2) OABCD. Simultaneously the primary current from the source g arises gradually from zero, according to the ordinary exponential law, as shown by the curve OVEFG in Fig. 2.

In all of these types of apparatus, using an electro-magnetically controlled oscillator, a is the magnet coil operating on a spring which controls the (vibrator break) oscillator b. Let OY^1 (Fig. 2) represent the current through the magnets necessary to produce a force equal to the controlling force of the spring. This is also shown at E. The magnetic force of the coil a, however, must be a little more than the force of the spring in order to control it. This is shown at F on the curve. When the primary current through the magnet coil a reaches this point F, the oscillator is opened.

So that there will be no sparking or arcing at the oscillator gap b, there must be no current flowing when it opens. Adding therefore the two current curves OABCD and OVEFG we get OHKEN, the curve of the total current through the oscillator b and the primary l of the transformer. This curve, it is seen, falls at zero when the ordinate NC is equal to the ordinate NF. It is therefore evident that by varying the capacity c, and the resistance R (which determine the curves OVEFG and OABCD respectively), it becomes possible to so adjust the factors that OHKEN reaches zero at the instant of rupture of the circuit, and under these conditions there will be no sparking at the oscillator.

The primary current through the coil a does not cease instantly, but slowly dies away as the condenser c charges up, such as shown by curve FP. This is the charging current for the condenser. We complete the corresponding curve CQR.

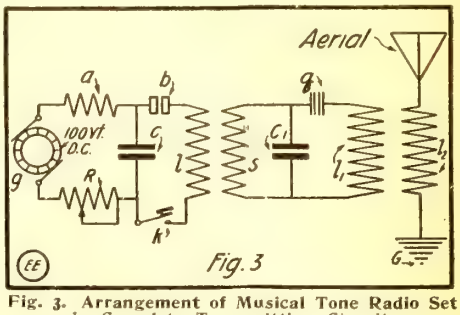

Fig. 3. Arrangement of Musical Tone Radio Set in Complete Transmitting Circuit.

This charging current flows through the coil a and serves to retain the oscillator spring; this keeping the oscillator open until some such point as S is reached, the ordinates OS being slightly less in value than OY_1. Here the oscillator closes again and the operation is repeated, commencing from the point O.

From the above it is obvious that the inductance a, resistance R, and capacity c, play important parts for the smooth operation of these instruments, and this is very well proven by experiment. Further, in order for the note to be a pure one, it is necessary that the second cycle must commence precisely at the point D (Fig. 2), and this can be attained by varying resistance R and the tension on the oscillator reed b.

Furthermore, it is at once seen that if the capacity c is increased, the curve FSP will decrease less rapidly and consequently the effective duration of the current through A, represented by distance ND, will be increased, and therefore the contact will remain open for a longer period, closing at some such point as T. But the

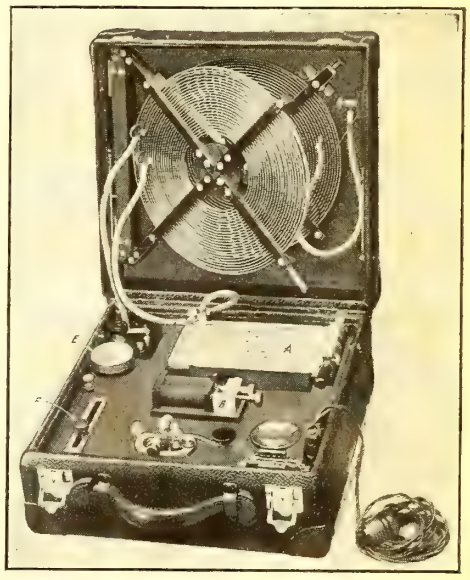

Fig. 4. Appearance of Commercial Dubilier Set.

curve OABCD will also have a greater time period, and will therefore approach zero at some point near T, so that the effective frequency of the oscillator is lowered. Resonance is then obtained by readjusting the primary resistance R, or spring

The Electric Arc and Its Interesting Applications

By Morton W. Sterns

THE electric arc is such an ordinary sight that one no longer stops to consider it, or any of its numerous interesting applications, but if the subject is followed up there is a field for much experimentation and extremely interesting research.

The object of this article will be, therefore, to open up a new field for research, it is hoped, and one that can be followed up with but little outlay for apparatus.

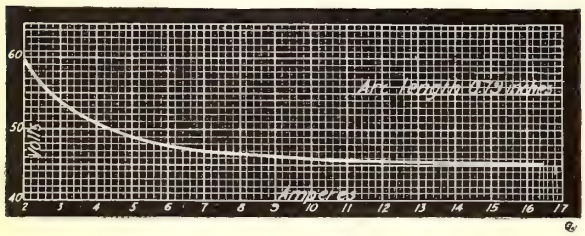

Fig. 1. Characteristic Curve of the "Arc" Showing Decrease of Potential with Increase of Current.

First of all let us consider the arc, what it is, and how produced.

Everyone knows that if two metal or carbon rods are connected to electric supply mains, brought together and then separated, current flows across the gap forming what is known as the electric *arc*. The current flows through the column of hot gaseous vapor, which is termed the *arc stream*, and flows from the positive or anode to the negative or cathode electrode.

The arc stream itself gives off a pale violet light, the useful part of the light coming from the luminous concave end of the anode in the case of the carbon arc.

If, however, the arc takes place between electrodes impregnated with various metallic oxides and salts the arc stream consists of the vaporized salts or oxides and becomes luminous at the high temperature of the arc; therefore in this case the arc stream gives off the greatest portion of the light, while the electrodes remain comparatively cool and do not give off an appreciable amount of light. This is known as the *luminous arc*.

By using various salts or oxides various colors can be obtained with the arc.

The electric arc between carbon or impregnated carbons can be maintained either by alternating or direct current, but it is very difficult to maintain an arc in which one or both electrodes are metal on alternating current, because the massive metal electrode cools so much faster than carbon that the metallic vapor is deposited and cools off each time the current goes through zero, thus preventing the formation of the arc during the next half cycle.

There is a property of the electric arc that is extremely important; that is, when the current through the arc *increases* the voltage across the arc necessary to maintain this current *decreases*.

This property is well shown in the curve of Fig. 1. This shows that it is necessary to always have a resistance connected in series with the arc to limit the current, otherwise due to the inherent characteristic of the arc, as shown by the curve, the current through the arc would increase indefinitely, constituting a short circuit.

This resistance is called the *ballast resistance*. On A. C. a choke coil may be used to limit the current.

One of the most familiar examples of the use of the electric arc is for illuminating purposes, and it is supplied in multitudinous shapes and forms. It is also an important factor in moving picture projection machines.

The arc is used in electric furnaces where very high temperatures are needed, as, for instance, in the manufacture of carborundum, a value of 7,500 degrees Fah. being obtainable.

Another application is in welding. Here the surface to be welded is used as one electrode, while a movable electrode held by the operator is brought into contact with it, forming an arc and thus causing the metal to melt and flow, thus closing up the cracks or fissures.

Another use of the electric arc is in the so-called "speaking arc." If the arc is connected up as shown in Fig. 2 and shunted by a telephone transmitter and a high resistance used to prevent the flow of excessive current from welding the carbon grains in the transmitter, thus rendering it inoperative, and words are spoken into the transmitter, the fluctuation of current in the transmitter circuit will cause a corresponding variation of current in the arc, thereby causing the arc to reproduce speech, music, etc. This property of the arc has been used to some extent as an advertising scheme by having a phonograph call out the wares for sale. Its greatest drawing power is due to the mystification of the passers-by as to where the voice emanates. They never suspect the innocent looking arc light suspended over the entrance.

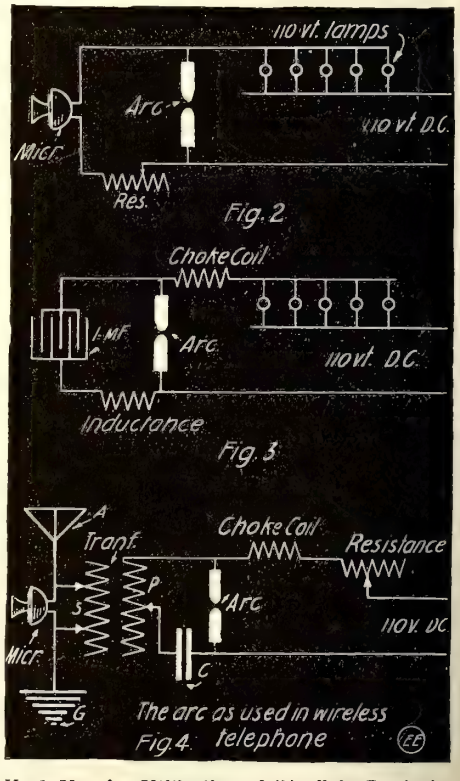
Another interesting property of the electric arc is its ability to produce high frequency oscillations and the easy means of adjusting the frequency.

There are innumerable forms of such arcs in use and to describe all would be tedious and unnecessary, as they all operate on practically the same principle. We will, therefore, consider the Chaffée arc. This type of arc has the advantage of being easy to construct, is very efficient and requires but little attention.

A simple form of Chaffée or "whistling" arc is made by using a copper beaker filled with water to aid in cooling for one electrode, and a carbon or piece of aluminum for the other electrode. This latter electrode can be fastened to a block of wood and the length of the arc is varied by moving the block to or from the beaker, while both are resting on a flat surface.

If the arc is connected up as shown in Fig. 3 and shunted by a capacity and inductance high frequency oscillations will take place in the circuit containing inductance and capacity.

The reason for this is as follows: When the arc is started current flows, and since a certain voltage exists across the arc the condenser becomes charged. Now if the current fluctuates an infinitesimal amount the voltage across the arc rises or falls, as shown by the curve (Fig. 1,), and the condenser either gathers a higher charge or else discharges across the arc.



Consider the arc as existing with a certain current flowing and a certain voltage existing across its terminals, the condenser therefore has a certain charge stored in it.

If the current should decrease an infinitesimal amount, due to some cause or other, such as the fluttering of a brush on the dynamo commutator, we see that the voltage across the arc rises, and this causes an increase in the charge of the condenser, since $Q = CE$, where Q is the charge stored in the condenser, C is the capacity of the condenser and E the voltage across its terminals. The current would come back to normal the next instant and since the charge in the condenser is greater than that produced by the voltage now existing across its terminals, the voltage having fallen as shown by the curve, the condenser would discharge across the arc in the form of an oscillatory discharge of high frequency. Hence there would exist in the circuit containing an inductance and capacity high frequency oscillations, while in the arc circuit we would have a pulsating direct current. An inductance or choke coil is connected in the supply to prevent the high frequency currents from reaching the D. C. generator.

For ordinary experimental use the type of arc described above can be used and shunted by a 1 M. F. condenser of the ordinary telephone type and an inductance consisting of a coil of No. 20 B. & S. copper wire wound on a form 3 inches in diameter and 12 inches long, tapped about every 25 turns, or else it may be fitted with a slider, as on the ordinary tuning coil, which, in fact, can be used to good advantage.

Now by varying the inductance the frequency can be varied, and this will be shown by the tone of the whistle produced by the arc.

All tones of the scale can be produced, and the frequency can be increased to above audibility. At this point it can be used in wireless telephony.

Hook-Ups for Utilization of "Arc" in Producing Speech, Music, Etc.

To use the Chaffée or "whistling arc" for wireless telephony it would be well to build a more substantial arc, using a copper tube with water circulating in it for one electrode and an aluminum bar for the other electrode. It will help somewhat to have the arc take place in an atmosphere of ordinary illuminating gas or hydrogen gas.

(*Continued on page* 595.)

DETERMINING THE LAG BETWEEN ARLINGTON AND KEY WEST RADIO TIME SIGNALS.

Although not generally known, there is an appreciable and measurable lag in the time signals sent out by the powerful Government stations at Arlington, Va., and at Key West, Fla. Special chronographic apparatus, with suitable recording attachments, have been installed at the Elgin National Watch Co.'s plant at Elgin, Ill. Frank D. Urie reports on the tests made at this point on the radio time signal lag in the Bulletin of the Astronomical Society. The distance between Arlington and Elgin is 700 miles and between the latter point and Key West 1,250 miles.

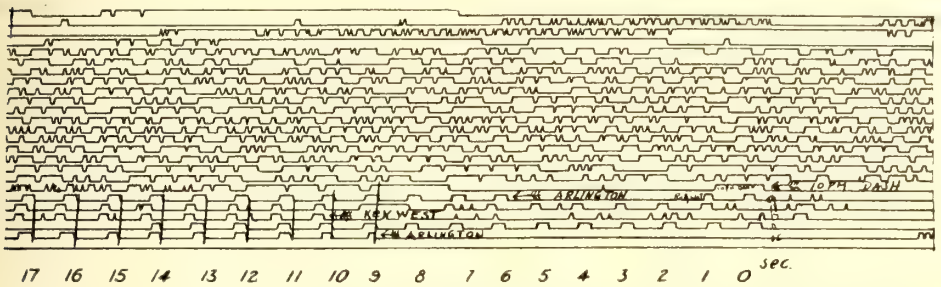


Chart Showing Record of Radio Time Signals and Lag Between Key West and Arlington.

A T-shaped aerial was employed at the Elgin plant, consisting of four wires, each 280 feet long and 150 feet high. To this antenna was connected a Telefunken receiving set, of the inductively coupled transformer pattern, using a galena detector.

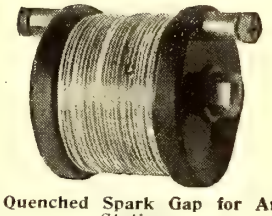
The detector current was lead to a series of amplifiers, which intensified the Arlington signals sufficiently to operate a very sensitive relay, the back contact points of which controlled a five-ohm pony relay, and this in turn controlled the chronograph circuit. The individual apparatus was carefully checked up and special means for compensating the differences in the operation of the instruments were devised by Mr. Urie.

The transmitting clock at the United States Naval Observatory sends the time signals by wire to Arlington and also to Key West. At each of these radio stations the wire signals are automatically converted into radio signals. Owing to the 900 miles of telegraph wire between Washington and Key West, involving several make-circuit relays, the Key West radio time signals lag perceptibly on the Arlington radio time signals.

While developing the radio recording device Mr. Urie found that it was possible to record at Elgin both the Arlington and the Key West radio time signals on the same chronograph sheet. The determination of the time lag between Arlington and Key West was undertaken in January, 1915, at the request of Captain Hoogewerff, superintendent of the United States Naval Observatory. During February the investigation was interrupted by the destruction of the Elgin (Ill.) antenna in a sleet and wind storm. The antenna was replaced as soon as possible and the investigation was continued through March.

The plan was to record the first minute of Arlington, then tune to Key West and record the second, third and fourth minutes; then tune again to Arlington and record the fifth minute.

The accompanying reproduction of part of the chronograph sheet of Jan. 29, 1915, shows how this was done. After the record was obtained vertical lines were drawn between the same seconds of the first and fifth minutes of Arlington. The lag of Key West could then be directly measured for every individual second. This method has the advantage that it eliminates entirely any errors in the teeth of the contact wheel of the transmitting clock, as the lag is always measured from the records of the same individual second.



The results of the lag determination are:

	No. of comparisons.	Lag of Key West.
Jan. 23, 1915.....	29	0.277 sec.
" 26, 1915.....	16	0.250 "
" 29, 1915.....	77	0.267 "
Mar. 8, 1915.....	22	0.240 "
" 10, 1915.....	48	0.120 "

Apparently there was some unusual lag on March 10 in the Arlington signals. This date has, therefore, been rejected in taking the average result of the determination, which gives the lag between Arlington and Key West as + 0.258 sec.

NEW QUENCHED SPARK GAP FOR AMATEURS.

A unique quenched spark gap has recently been put on the market which undoubtedly will find favor among radio experimenters. As is well known, the quenched spark gap is one of the very best available for this class of work and it produces a pure wave, as required by the United States radio law now in effect, and besides has several other valuable inherent characteristics.

New Quenched Spark Gap for Amateur Stations.

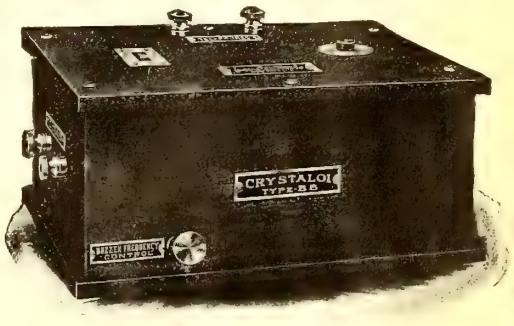
The quenched gap in question is shown in the illustration herewith and measures 2¾ inches long by 1⅞ inches in diameter, having 24 gaps of standard length, viz.: .01 inch each, and thus the gap will handle about 24,000 volts, such as from a spark coil, etc. A less number of gaps than the total number may be readily used in the circuit by leaving one wire connected to the end terminal, and the second connection from the condenser circuit is secured around one of the brass plates making up the gap. For high power sets using transformers several of these gaps are connected in series-parallel, to accommodate properly the amount of energy passing through the circuit.

This gap, as may be observed, is composed of two fiber end discs carrying the binding post terminals and each of these is clamped to the end gap plates. Between every two metal plates there is inserted a mica washer of the proper thickness and these are so perforated as to provide a true vacuum gap between the spark plates. This, of course, is absolutely necessary if the quenching is to be performed in the proper manner and as necessitated in the action of this particular piece of apparatus. There are some gaps on the market that are termed quenched gaps by their sponsors, but in reality they are no such thing, as the sparking electrodes are placed in the open air. This gap is readily assembled and disassembled by means of a strong center bolt and nut which clamps the whole together firmly in one operation. It is also well ventilated inside and outside, as there are several holes drilled through the fiber end discs, thus providing double ventilation.

SAYVILLE WIRELESS WORKING AGAIN.

Wireless communication via Sayville, N. Y., is restored and messages can again be accepted to go by wireless via Sayville to Germany, Austria-Hungary, Turkey and non-belligerent countries.

A COMPACT RADIO DETECTOR CABINET.



In the new detector cabinet here illustrated there is embodied in a single unit every element necessary to rectify into audibility any wireless signals you care to hear.

This set consists of a highly finished mahogany case in which is located a supersensitive Crystaloi detector cylinder, the periphery of which protrudes through the top, making it accessible for rotating to secure finest adjustment. A cohering inductance especially calculated and calibrated to the supersensitive detector is included, as well as a fixed condenser with the exact capacity for this particular instrument. A specially wound buzzer, the frequency of which is controlled by a knurled screw head mounted on the front of the case to produce a note that is best suited to assist in cohering the alloy in the cylinder is mounted within the neat cabinet, also two of the highest grade dry batteries to operate the buzzer. A buzzer control button protrudes through the top of the case for accessibility.

This case is equipped with four binding posts, two of which are for the 'phones and two for the tuner leads and is provided with anti-shock feet which renders it immune from mechanical shocks and jars.

The specially wound buzzer has an adjustable frequency range of 1,000 to 2,000 vibrations per second.

With this carefully designed and calibrated instrument you have but to set it on the table, connect your 'phones and leads from your tuning coil and you are permanently and thoroughly equipped to engage in the most serious wireless work of the present day. Of course, variable condensers can be added if desired. The fact that every part of this apparatus is designed, built and proportioned to work with each other makes it a superior piece of wireless mechanism.

Neat Radio Detector and Test Buzzer Set.

Manager, H. Gernsback

The RADIO LEAGUE of AMERICA

HONORARY MEMBERS
CAPT. W.H.G. BULLARD, U.S.N. NIKOLA TESLA.
PROF. REGINALD FESSENDEN. DR. LEE DE FOREST.

Subsidiary Radio Clubs.

SINCE the formation of the RADIO LEAGUE OF AMERICA two months ago we have been asked by a great many local Wireless Clubs as well as by local Wireless Associations if these organizations could become directly connected with the LEAGUE in some form or other.

As the LEAGUE champions the cause of all Radio Amateurs, without exception, it is highly desirable that every radio club should become directly affiliated with the LEAGUE. The RADIO LEAGUE OF AMERICA being a central body, organized to bring all the Amateurs together, to ward off hostile legislation and to serve the United States during peace as well as during war, it is in an excellent position not only to benefit every Amateur, but every local club as well.

It is highly probable that the future will see new attempts to curb the Amateur. Hostile bills will certainly be introduced in Congress, and it is one of the first duties of the RADIO LEAGUE OF AMERICA to safeguard the Amateur's rights. No other body is in such an excellent position to do this as the LEAGUE. No other body can obtain facts quicker or better than the LEAGUE. Therefore, if all the local clubs and associations are directly affiliated with the LEAGUE, only good can come of it.

Of course this is not the only reason. Suppose that every club and all its members were directly affiliated with the LEAGUE. Also suppose that, for obvious reasons, the Government should wish to mobilize all the Amateurs, be it for a test maneuvre or for actual eventualities. Would not the LEAGUE be in a paramount position to quickly convey such intelligence to the affiliated clubs and its members? Naturally this can only be effected in a satisfactory manner if the names of the clubs are on file and if its members are enrolled in the LEAGUE.

In order that a club or association can become affiliated directly and permanently, the following is required:

The president as well as two officers of the club must be members of the RADIO LEAGUE OF AMERICA. Upon application to the manager of the LEAGUE, a special certificate will be made out to the club and this certificate must be constantly displayed at the club's headquarters.

A special form of application blank as well as detailed instructions will be furnished by the manager of the LEAGUE upon request to the secretaries of local clubs and associations.

It is, of course, understood that there are no fees, or membership dues to be paid to the LEAGUE either by the club, by its officers or by its members. The manager hopes to hear from every club and every association in due time.

Formation of New Clubs.

We stated in our December issue how exceedingly simple it is for Amateurs to form new clubs. As the RADIO LEAGUE OF AMERICA now has above 5,000 members scattered all over the United States, it becomes an easy matter to bring Amateurs together.

As an example, suppose you live in Springfield, Ohio. (This city was taken at random.) As all records of members' names of the LEAGUE are filed geographically, the writer is informed that there are 19 members enrolled from Springfield, Ohio. Offhand we do not know if there exists a Radio Club in Springfield, but let us assume there is none as yet. Also let us assume that you are a live and wide-awake member living in Springfield. By sending a stamped return envelope to the manager of the LEAGUE and stating your desire, the LEAGUE will furnish you, free of charge, with the names of 19 members. You can thus easily get into touch with them, and a new club may be formed in this manner with but little trouble.

In our March number will be found one of the most elaborate articles ever printed on how to form and manage a Radio Club. It will be exceedingly well illustrated with pictures of existing clubs, their radio equipment, etc., etc.

In that issue will also be found a complete Directory of Radio Clubs in the United States. Do not miss this issue.

To Members of the R. L. O. A.

Those members not having received their membership blanks till recently will kindly excuse the delay. The first 1,200 blanks were promptly mailed in the middle of December. This amount represented the entire supply delivered, as our lithographer had an unfortunate accident in breaking the stone from which the certificates are printed. This naturally caused an unavoidable delay, and for that reason the balance of the certificates could not be mailed before the middle of January. We now have a large supply at hand, and if by chance anyone should not have received his certificate the manager will be glad to look into the complaint at once.

To Radio Clubs.

As announced above, the March issue will contain a complete Directory of all Radio Clubs in the United States. We will publish the names of all clubs about which announcements have been published in *The Electrical Experimenter*, as well as in other journals in the past. In order to make the directory complete, those clubs not having been announced in the wireless and kindred journals will kindly communicate with the manager of the RADIO LEAGUE at once. The benefit that the clubs and associations will derive by being listed in the Directory is obvious. *The Electrical Experimenter* now prints over 53,000 copies monthly and is read by over 150,000 wireless enthusiasts. It is by far the most widely distributed Wireless Organ, barring none, in the world.

* * *

Complete information of the RADIO LEAGUE OF AMERICA, its purpose and its plans will be mailed free for the asking. Every American Wireless Amateur is eligible as a member. Beautiful membership certificate free to members. The LEAGUE is not a money-making organization. There are no fees, no membership dues, etc. WRITE *TO-DAY*.

BROOKLYN, N. Y., YOUTH MAKES VALUABLE RADIO INVENTION.

Government experts recently concluded their tests as to the practicability of the under water telegraph device for submarines, invented by Elmer Matthew Rave, of Brooklyn, N. Y., and reported to Secretary of the Navy Daniels that the device passed every test. The inventor, 20 years old, offered the invention to the Government for a sum total of $275,000.

Young Rave has received many offers from foreign governments for the mechanism which is designed for the protection of sailors in submarines. The most flattering was made, it is understood, through D. Fedotoff, naval attache of the Russian Imperial Embassy, but Rave decided to offer it to the United States before considering any offer from foreign nations.

The tests covered a period of some weeks and were very exhaustive. The Government officials were given strict instructions to go to the bottom of the matter and find out if the invention was at all feasible and practicable. Their report is exceedingly gratifying to Mr. Rave.

This invention, which will be controlled by wireless, will take the place of the present submarine sound signaling bell system, now in universal use in submarines. It will enable a crew of a submarine, while submerged, to communicate by wireless with other ships or stations. In the case of an accident under water it will admit of a call for help.

Rave is a graduate of Commercial High School, Brooklyn, and has been working on the invention since the disaster to the submarine F-4 in Honolulu Harbor.

9,000-MILE RADIO A NEW RECORD.

What is stated to be a record in radio transmission was established on Nov. 29 last, when an operator for the Federal Wireless Telegraph Co. at Honolulu picked up wireless messages being transmitted from Nauen, Prussia, to Tuckerton, N. J., approximately 9,000 miles away.

The German operator was sending war despatches, and the dots and dashes registered so clearly in the Honolulu radio station that the eavesdropper had no difficulty in copying the report.

TO ISSUE NATIONAL EDITION OF LIST OF RADIO STATIONS.

The United States Bureau of Navigation, Department of Commerce, has in the hands of the Public Printer, its annual edition of the "List of radio stations of the United States," containing a list of 5,073 stations. The table here given shows the number of land, ship, special land, and amateur stations in this publication, as compared with that of 1914:

Classes of stations.	1914.	1915.	Increase.
Government and commercial land stations	189	224	35
Do. ship stations	895	895	0
Special land stations.....	54	118	64
General and restricted amateur stations 2,796	3,836		**1,040**
Total 3,934	5.073		1,139

The appendix to this list contains several articles of interest to radio operators. The book, which has been available since Nov. 1, may be procured from the Superintendent of Documents, Washington, D. C., at 15 cents per copy. Copies of the "Radio-communication laws and regulations" may be procured from the Superintendent of Documents at 15 cents per copy.

THE CONSTRUCTOR

Construction of a Collin's Radiophone Arc

By H. Winfield Secor

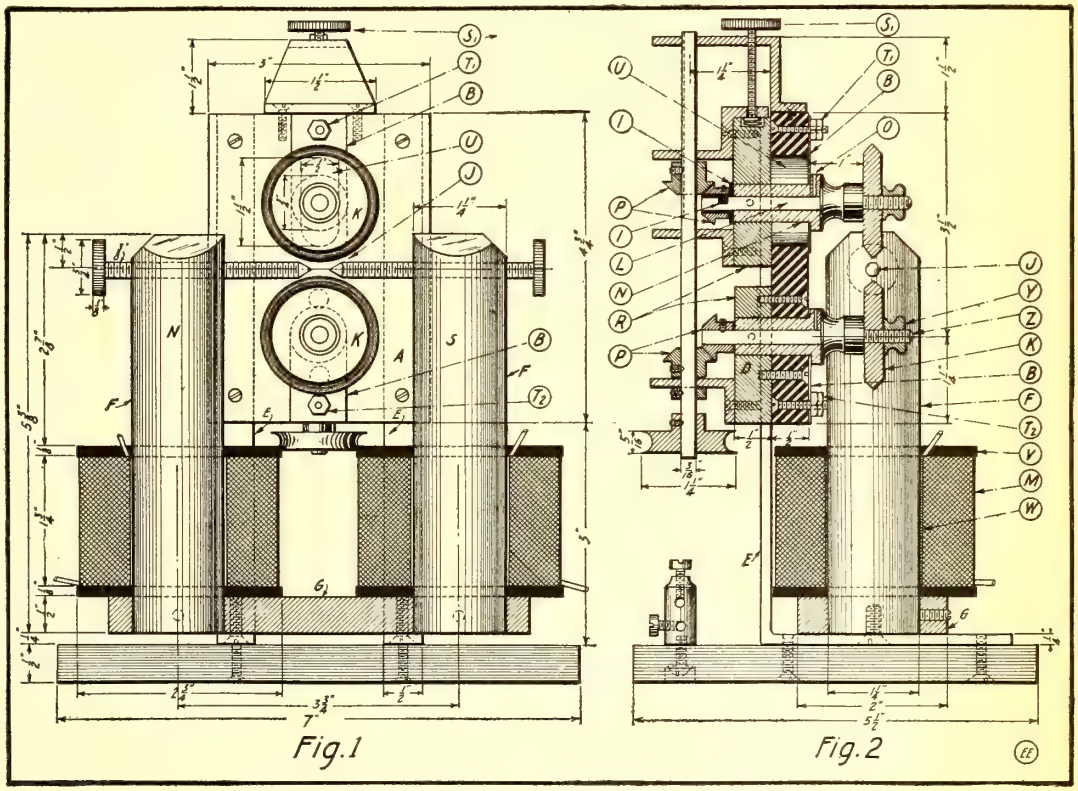
WIRELESS telephony is possibly the most interesting branch of science with which the radio and electrical experimenter comes in contact. Herewith directions are given for constructing a Collin's Oscillating Arc, adapted for generating high-frequency currents well suited to experimental radiophonic requirements. Such an arc generator as here described can be made up quite cheaply, and, moreover, is of such design as to permit of a wide range of interesting experiments, such as enclosing the arc proper in a gas-tight chamber in which hydrogen, alcohol or illuminating gas can be used; also, the arc has been found to operate very satisfactorily in an envelope of steam.*

The constructional details of a Collin's Oscillating Arc generator are given in the illustration herewith presented. This arc, it may be said at the start, utilizes graphite discs, which rotate at fairly high speed, and the arc proper is sustained between their rapidly moving peripheries. Graphite has been found, after extensive tests at the United States Bureau of Standards laboratories, to be absolutely the best material for such an arc, especially when it is to be used for considerable periods, and to produce oscillations steadily without frequent readjustment of the apparatus.

The dimensions of the apparatus here suggested may be deviated from to some extent, without any detrimental effect, so long as the principal features are incorporated in the make-up of the whole. Referring to the working drawings (Figs. 1 and 2), A is a slate or asbestos composition switchboard about ½ inch thick. B is a brass strip making contact with the brass or phosphor bronze bearings N, in which the spindles carrying the rotating graphite discs revolve. A fiber or hard rubber block R is indicated, which has a width of 1½ inches. This carries the bearing N, also disc K, pinions P, etc., and may be moved up and down when adjusted by the screw S_1 at the top of the arc generator. A fiber or hard rubber block is denoted at D also, being about 1½ inches wide. Wrought iron or brass supports E are made up from ¼x½-inch stock or slightly heavier, if available.

The magnetic blast for this arc comprises wrought iron magnet cores F fitted to a wrought iron yoke G. Insulation on the varius parts of the apparatus, such as around the pinions, etc., is indicated by I. This is to prevent electrical connection between the pinion and shaft L, etc. Long machine screws, carrying large-sized knurled heads, are observed at J, the ends of same being ground or filed to a point, with about a 60-degree taper. These points face each other and are so arranged as to project between the revolving graphite discs.

At K is seen the graphite arc discs, made up from ¼-inch or ⅜-inch stock, with a diameter of about 2 inches. Carbon may be used, but it will not give the results obtainable with graphite. These discs are rotated by the shaft at the rear of the apparatus, which is driven by belt from a small fan motor at the rate of 400 r. p. m. or more. The arc length is varied by means of the adjustment screw S_1 and the charteristics of the arc may be changed also by adjusting the magnetic blow-out poles J.



At the rear of the instrument there is a vertical iron or brass shaft L. This may be about 3/16 inch in diameter. It carries the small brass pinions P, the upper one of which is provided with a key, which slides in a key-way cut into the shaft as indicated in Fig. 2. This permits the upper electrode block R, together with the upper pinion P, to slide up and down the shaft while the latter is rotating. This arrangement will permit of adjusting the arc length while it is in operation, as becomes evident. All of the gear pinions P are of the same pitch (say about 32 pitch) and have 16 teeth per pinion.

The magnetic blow-out coils M each contain nine layers of No. 12 B. & S. double cotton-covered magnet wire. The two coils are connected in series to give north and south poles, respectively, at the adjustable electrode terminals J. The iron cores on which the magnet coils are wound are first insulated by winding three layers of Empire cloth around them.

The brass or phosphor bronze bearings N are provided with oil holes O. The upper bearing is movable up or down in a slot cut in the board A. The terminals of the arc proper are indicated at T_1 and T_2, either one being used for the positive electrode, according to the best result with respect to the polarity of the magnetic field applied.

It may be well to state that this arc should never be started—i. e., the current should not be applied to the rotating graphite electrodes—until they have been speeded up to a high velocity. Greatly enhanced results will be obtained with this or any arc generator if the arc proper is burned in an atmosphere of hydrogen or other vapor, and some vital points in this direction are cited later on in this article.

The diagram of connections for this arc generator intended for radio-telephony is observed at Fig. 3. Referring to this more in detail, CK are choke coils comprising soft iron wire cores 8 inches long by 1 inch in diameter. These are covered with three layers of Empire cloth, and over this three layers of No. 12 B. & S. insulated magnet

Working Drawings of Collin's Radiophone Arc Generator.

* See Reprint No. 60, Bureau of Standards Bulletin, "The Production of High Frequency Oscillations from the Electric Arc," by Dr. L. W. Austin.

wire is placed, taps being taken from each layer so as to allow for adjusting the choking effect. This arc may be used on 110 to 220 volts direct current, or even a higher voltage providing a sufficient resistance R is utilized to control the current properly.

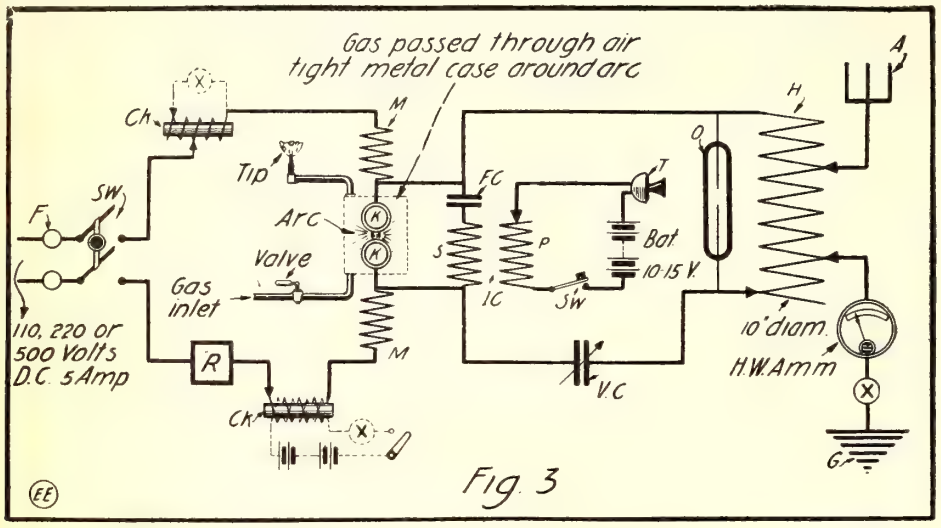


Fig. 3

Diagram of Connections for Wireless Telephone Arc.

VC is a rotary condenser of standard pattern, filled with *castor oil*, which has the effect of increasing the insulation of same and also of raising the capacity to about five times the original value, with air dielectric. The helix shown may comprise 30 turns of No. 6 brass or copper wire wound on a wooden frame 16 inches long and 10 inches in diameter, spacing the turns one-half inch apart. Suitable clips are used to permit the use of as much of the helix inductance as required. An instrument for indicating the maximum oscillations produced in the shunt arc circuit and known as the "oscilloscope," is shown at O. This may be purchased from any electro-therapeutical concern at small cost, but this is not necessary for general work.

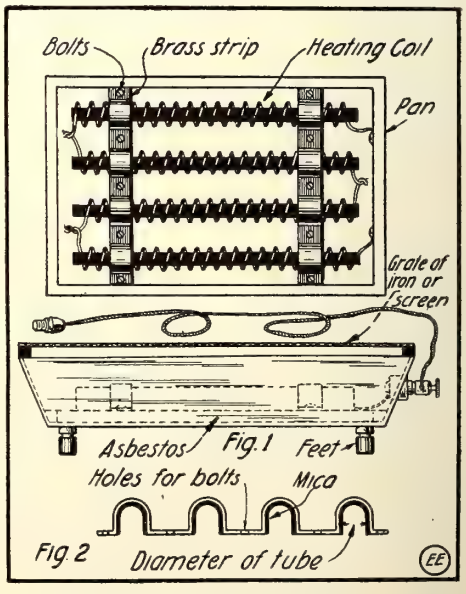
The optional locations of the microphone transmitter T are indicated at points X X, etc. A common location for the microphone or transmitter is in series with the ground lead, as is also that for the hot wire ammeter. A method employed more or less for superimposing the voice currents on the arc circuit, utilizes an induction coil I C, which may be a ¼-inch spark coil. If this is not available a suitable induction coil may be made up with the following dimensions: soft iron wire core 5½ inches long and ½ inch in diameter, insulated with two layers of paper. A primary winding is wound over this, consisting of two layers of No. 20 B. & S.—D. C. C. magnet wire. Wound over the primary are six layers of Empire cloth and then the secondary coil, consisting of four ounces of No. 36 B. & S. enameled magnet wire is wound in place. This may be put on with paper between each layer. A fixed condenser, F C in the microphone superimposing circuit, may be made of three or four pieces of Empire cloth, each 8x10 inches — 1/100 inch in thickness, or 10 mils. These sheets are coated on both sides with slightly smaller tin-foil and the whole is then laid together with connections made to alternate tin-foil leaves, in the usual manner.

If illuminating gas is used in the gas-tight chamber placed around the arc, a good scheme is to provide a gas tip leading out of the chamber. The tip is lighted, as here indicated, for this is conducive to the best circulation of the gas through the chamber.

This set may be used on any size antenna, but, of course, the longer and higher the aerial wires, the more pronounced the results will be as regards the talking range. Any wireless receiving set will pick up radiophonic speech and this arc generator is capable of talking 20 to 25 miles when properly operated with a gas enveloped arc.

In case it is desired to superimpose the voice current on one of the choke coils C K, a secondary winding may be wound over the outside of the choke coil winding proper, as indicated; X being microphone and a battery, of course, being connected in series with the coil and the transmitter. This secondary coil may consist of three layers of No. 18 B. & S. insulated magnet wire and several layers of Empire cloth, or waxed paper should be interposed between the two windings.

Dr. L. W. Austin has ascertained that for a simple arc generator, graphite electrodes are better than most any other material, especially where steady oscillations are required for making quantitative observations and tests. The various circuit quantities employed in one of Dr. Austin's researches were as follows: Primary circuit of arc: Electrodes—graphite, flat ends, diameter 12 mm.; resistance in series with arc about 50 ohms; arc current 4 amperes; potential difference across arc 26 volts and across open circuit 242 volts; arc length about 0.3 mm.; inductance in shunt circuit .009 milli-henry; capacity 0.4 m.f.; alternating current in shunt 4.0 amperes. Secondary (inductively coupled) test circuit values: Inductance 0.168 milli-henry; capacity —variable; resistance circuit 7 ohms; current 0.1 to 0.2 amperes. With these conditions it was found that the arc would easily produce oscillations steadily for periods of one-half hour or longer. When the frequency was measured by the secondary resonance circuit, it was found that there were present well-marked maxima corresponding to frequencies of 205,000, 580,000 and 910,000 cycles per second. The lowest frequency appeared to carry the largest part of the energy, while the highest was the weakest. The frequency calculated from the inductance and capacity of the primary circuit; *i.e.*, shunt oscillatory circuit of the arc was 260,000 cycles per second. He was unable to find any other frequencies present, but the possibility of such seemed fairly certain.



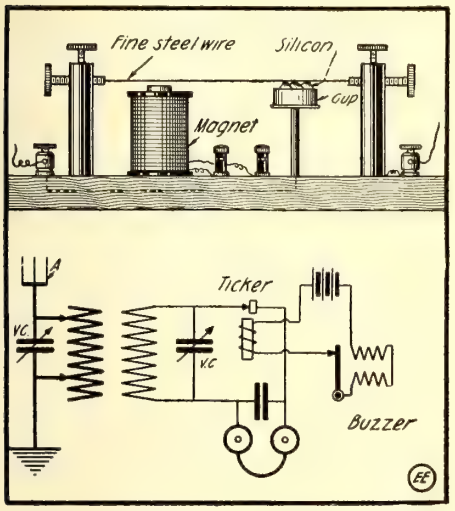
Burning the arc in hydrogen after Poulsen's method, Dr. Austin found, caused the more rapid production of oscillations, also permitting of a longer arc length or up to 0.8 mm. in the case of graphite at 240 volts line potential. Marked indeed was the increase of the amount of energy which could be drawn from the oscillating circuit. With the graphite arc in air only about 6 to 8 watts were available, but by utilizing a hydrogen envelope, over 100 watts could be drawn; in one experiment bringing a 110-volt—32 c.p. lamp to full brightness.

It seems that the effect of the hydrogen gas on the arc is partly due to the high heat conductivity of the gas, which thus helps to cool the electrodes. Poulsen claims, in addition to the cooling effect, that there is a marked influence on the electrical conductivity of the arc, which he considers of great importance. With the arc in steam all the benefits derived from hydrogen were readily duplicated. Oscillations of great power were also observed when the arc was formed under water, where the steam was produced by the heat of the discharge. Satisfactory results have been obtained with the arc burned in compressed air also. The arc, although ordinarily unstable, has thus been found to be a most satisfactory source of undamped waves for wireless purposes. Moreover, it is a device available to most all radio experimenters, and they will indeed find their time well spent in trying it out.

HOW TO MAKE AN ELECTRIC TOASTER.

The most palatable toast is said to be that made upon an electric toaster. The toaster herewith described can be constructed by anyone.

Procure a common bread pan or other metallic dish. Next obtain a piece of asbestos board ½ inch thick and just a trifle smaller than the inside of the pan. Place the asbestos inside of the pan and drill 10 holes in the bottom for tube clamps, as shown. Now obtain four porcelain tubes and upon each one wind about 30 turns of No. 24 German silver wire. Two strips of brass made, as shown in Fig. 2, are used to clamp the four resistance coils to the pan by means of ⅛-inch stove bolts and nuts. The coils are connected in series and the two end terminals are brought to two insulated binding posts as shown. Care should be taken to see that the binding posts do not touch any part of the pan, using mica or fibre washers around their securing screws. A small grate or screen of iron is made for the top of the toaster.



Details of Electric Toaster.

The wire should get red hot in a minute or so and by using less turns of the resistance wire in circuit the heating effect will be increased. Four porcelain knobs should be placed at the corners to raise the pan above the table. The drawing is self-explanatory. This toaster is intended for use on 110 volt circuits.

A SILICON "TIKKER."

Many radio amateurs, especially those living in the Eastern States, cannot catch Arc signals. The tikker, of which I give a drawing, is just the thing. A buzzer must be put in the circuit of the magnet to make the necessary interruptions. Build one, boys, and see what you have been missing!

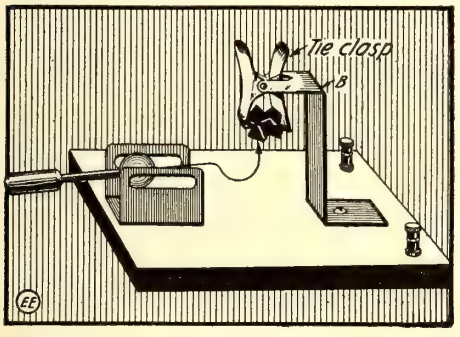
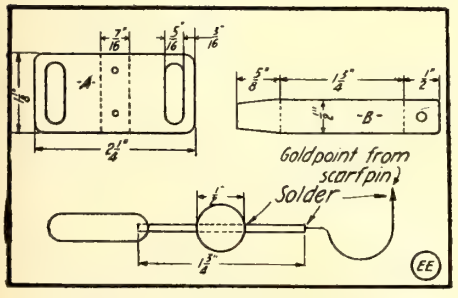
LEIGHTON JOHNSTON.





Tikker Comprising Steel Wire Vibrating Against Silicon.

A NOVEL DETECTOR.

Following is a description of a detector I made with which you can touch every part of the crystal by simply moving one knob.

First get some $\frac{1}{16}$-inch springy brass and cut to the shape shown at A. The openings can be made by first drilling holes and then filing. Then bend on dotted lines. Now get a brass ball ½-inch in diameter and drill a hole through it to admit the brass rod which has a thread on one end to take the knob. The ball and a piece of fine brass wire are soldered

Ball Adjustment for Mineral Detectors.

on the rod. I find the point from a gold scarf pin to be very sensitive as a "cat-whisker" and it does not tarnish. The standard, B, is made from heavy brass and the tie clasp is soldered on to hold the crystal. The inverted position of the crystal keeps the dust from settling on it and thus causing it to lose its sensitiveness. The base can be made from hard rubber or hard wood. Parts A should be tight enough to keep the ball in place. The knob can be moved back and forth or in any direction.

Contributed by G. F. EXNER.

MONEY-SAVING HINTS FOR THE EXPERIMENTER.

Electrical apparatus of all kinds involves an outlay of money which soon runs into quite appreciable amounts—at least to the junior mechanics. A few suggestions along the line of procuring some necessary materials may be of help in cutting down expenses to a minimum.

Fine resistance wire, for instance, is costly when bought at the supply houses, but a very cheap substitute that will do the work well, providing the working temperature is not too high, is the wire used in making galvanized window screens. This can be unraveled easily from a piece of screen, and the wire is continuous. I have made several small rheostats from this material and they all work well.

The brass lining of an old Ford automobile wind shield makes good slider rods for tuning coils, potentiometers, etc.

It is a good plan to save all old battery bolts, binding posts, connectors, brass ribbon, wire, etc., as they will prove useful at one time or another.

The rubber casings of discarded storage batteries may be employed to advantage in several ways. The sides may be cut out with a hack-saw and scraped and polished. These make good detector bases. If the case is unbroken it makes a good container for a small condenser which is to be immersed in oil.

Cheap sending condensers for spark coils up to one inch capacity can be made from small test tubes. The six-inch size is preferable. They should be coated inside and out to within one-half inch from the end with tinfoil. A tinfoil lead may be used as a connector to the inner coating by bringing it out through a hole in a paraffined cork plugged in the opening.

Supports for the terminals of a small spark gap can be made from the lightning arresters on old-fashioned telephones. These consist of three large binding posts, with a half-inch hole drilled transversely through each for holding the carbon rods. Zinc may be used in place of the carbon rods, and a series gap is the result.

An efficient ground connection can be made from a 1½-inch galvanized iron pipe which has been burst by freezing. A cap should be placed on one end and the pipe driven into moist ground to a depth of at least six feet. Strong salt water should be poured into the open end of the pipe until the earth near the pipe is thoroughly moist. The ground wire may then be soldered to the top of the pipe or secured by means of a clamp. Water must be poured down the pipe frequently for best results.

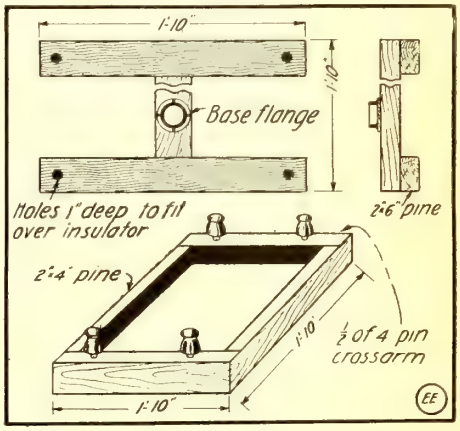
1,000 FEET COLLAPSIBLE RADIO MAST.



Push a button and, presto—you've got a wireless tower 1,000 feet high. Such a tower is under consideration by the United States War and Navy departments for adoption as part of the new national defense scheme. The inventor is Joseph Raes, an American citizen, native of Belgium, now living in Washington.

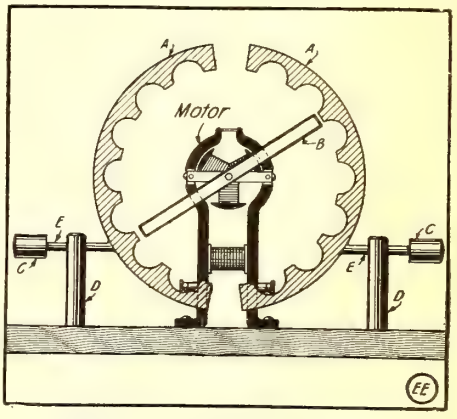
The tower is made of steel tubing, like a giant collapsible fishpole. It can be mounted on a concrete base; smaller towers can be attached to motor trucks.

Each tower has guy wires attached to powerful springs, which coil up the guys when the tower is "down." When the tower goes "up" the guy wires and harp strings for the wireless are spread automatically. It is strong enough to bear searchlights, machine guns and signaling apparatus.

INSULATED AERIAL MAST BASE.

To insulate the base of my iron pipe mast I took a four-pin cross-arm and sawed it

Insulated Antenna Mast Base.



in two. Over this was placed a base made of yellow pine bored to fit down over the isulators about 1 inch. I use high tension porcelain insulators on the pins. By referring to diagram the base can be very easily made.

Contributed by P. F. RUTHERFORD.

UNIQUE ROTARY SPARK GAP.

The parts necessary to construct this rotary gap are as follows: A small motor, a sheet of brass 6 inches square and ⅛ inch thick, two large binding posts, a piece of brass 5x1x⅛ inch, a piece of brass rod 6 or 8 inches long and ⅛ inch in diameter. A—Stationary electrodes, which are cut out of the square sheet of brass. B—Rotating bar, which is fastened on the motor shaft. C—Hard rubber knobs. D—Large binding posts. E—Brass rod.

To operate this gap the rod which is fastened on A is put through the hole in

Effective Type of Small Rotary Gap.

the binding post and then adjusted as near the rotating bar as seems best, and to be found by test. The motor can be a common battery motor.

WRECKED.

The explosion of an alcohol tank wrecked the Naval wireless station at Cordova, Alaska, recently and caused the injury of three enlisted men, according to a report received at the Navy Department.

AN ELECTRICAL HAND-SHAKING SURPRISE.

I have decided to contribute an idea of mine with which I have had all kinds of fun. It is a hand-shaking, shocking device which works to perfection. Observe the drawing, which I have made very simple.

The most important thing is the induc-

Apparatus for Electrical Hand-shaking Surprise.

tion coil, which can either be purchased or made as follows: Cut some soft iron wire into 3¾ inch lengths and make up a bundle ⅜ inch in diameter. Cut out two pieces of wood, one 1½ inches square and the other 2½ inches by 1½ inches by ¼ inch. Bore ⅜-inch holes through centers, fit in the core and soak the whole in melted paraffine wax. Now wind on this two layers of No. 22 wire and run the ends out through two small holes in the larger end. This is for the primary and the vibrator, which can be bought or taken out of an old electric bell. One wire goes direct to a screw, A, at the top of the vibrator end, and the other goes to the thumb screw B. The vibrator spring is connected to C. Next wind two layers of writing paper over the primary and glue it. The secondary is next wound on. Make a small hole D in the smaller wood end and run out wire and connect to E. Wind on two and one-half to three ounces of No. 34 magnet wire evenly and connect to other terminal F. Next wind three or four layers of paper over this and glue. So much for the coil. Now cut out a piece of wood 2 inches by 1 inch by ¼ inch and fasten on two metal plates separated about ⅛ inch. Connect a wire to each plate and leave about 3 feet over. Next take a flashlight case and instead of a lamp obtain a miniature attachment plug.

To work it put the flashlight case and battery in the left trouser pocket and run the wires from the attachment plug to the primary of the coil, which is placed in a vest pocket, vibrator up. The wires from the hand-plates are run up the right sleeve and connected to the secondary of the coil. To test it, press the button of the flashlight and the buzzer on the coil should start, if not adjust it. Then place the piece of wood with the plates on the palm of the hand and you will feel the shock. When shaking hands with anyone turn the piece of wood so that when the hand is grasped the plates will touch the victim's hand and then watch results! I have used my apparatus for nearly a year and have had great fun with it.

HINTS ON USING ODDS AND ENDS IN RADIO CONSTRUCTION.

Interest in radio experimenting centers in the ease with which efficient apparatus can be made up by the average boy, who generally has few tools and little cash. Discarded clocks, bells and batteries, and other miscellaneous material, generally classified as "junk," can be worked over into radio sets.

Zinc from old batteries, melted under charcoal, is cast into new zincs; the side binding posts from dry batteries, hacksawed off at the bottom of the slot in the head, and held in a lathe, are filed into shape for switch points. When there is no lathe, a hand drill held in a vise answers the purpose.

Carbons of old batteries are renewed by boiling in clean water. The connecting screws are very useful.

Old wire, from bell magnets, et cetera, can be used for tuner windings; if the insulation is damaged, wind a thread between turns. Sealing wax and a hot soldering iron will fasten the ends.

Old photo films, boiled until clean, make good condenser dielectrics for receiving circuits.

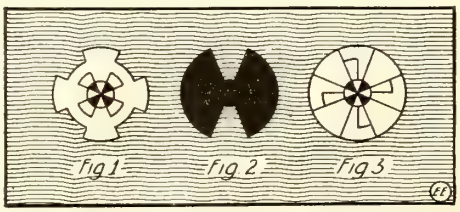
Hard rubber may be softened by inserting it in boiling water; form while hot. Warped pieces may be straightened by heating, and clamping between smooth boards until cold. Any tool used in woodworking will work on rubber, but must not be crowded or forced.

Instruments made of wood should have all metal parts separated from the wood by mica sheets or washers, so that at no point in the circuit does the metal rest on wood.

Use a pure silver wire for "cat-whisker" detectors; all metal parts should be silver-plated, which can be done at home with little trouble. Nickel is a loss.

Exploded cartridge shells can be worked into good detector cups.

Aerial masts can be made nicely of three by one-inch wooden strips, built in a long V shape. Latticed across in four to six-foot lengths, they are light and strong.



Discarded lengths of the galvanized cable used by electric companies as guy wires, when untwisted in pairs, make excellent guy wires for the ordinary mast.

Aerial ropes boiled in paraffine last longer, without stretching and shrinking from the weather.

Contributed by A RADIO BUG.

AN ELECTRIC DISC ILLUSION.

I give herewith a contribution to the *The Electrical Experimenter,* by which many wonderful and charming color illusions can be produced both day and night. The plan of construction follows: Articles necessary —A small motor, a wooden cabinet, three or four cells of battery, a switch, a sheet of metal and a piece of cardboard about 10 inches long and 7 inches wide. First of all mark out in dotted lines the two revolving color discs as illustrated in Figs. 1 and 3.

Details of Color Discs.

A sharp penknife must be used in order to trim away the edges and ends in the disc illustrated in Fig. 1. Then procure a sheet of brass or metal, mark out and cut out as shown in Fig. 2. In every one of these discs leave a small hole in the center in order to permit their fastening on the shaft of the motor loosely. Then make a sort of cabinet of wood as shown in Fig. 4. In the center of the top of the cabinet drill a small hole in order to pass the shaft of the motor through. After doing this, fasten your motor on a block of wood and again tighten this block, with motor attached, on the base of your cabinet. (See Fig. 4.) Then con-

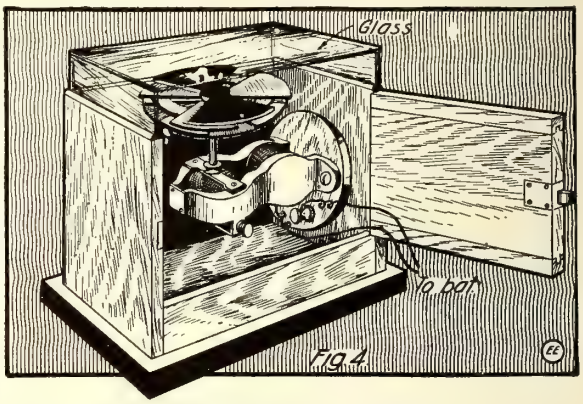


Fig. 4. Assembled Electric Disc Illusion Apparatus.

nect with batteries and switch as usual. At last paint the cardboard discs with a variety of bright hues, each one different, and fasten all three discs on the shaft protruding from the hole you drilled in the cabinet. With the addition of a plate or pane of glass the effects of the colors are greatly increased. This plate or pane can be supported by four felt or rubber-headed tacks driven in at the four corners of the cabinet. By night this outfit may also be used, but the discs must be especially made for this purpose. Cut out neatly and accurately with a sharp penknife all the curves and bends in Fig. 1 and 3, so that a mere outside frame or skeleton of the disc is left. Now take some thin tissue paper and paste it on the back of the skeletons of both discs. Then paint them with various different bright tints. On the top of the cabinet mark out and draw a circle with a compass and drill in as many holes as can be made on the circle just drawn. Then a bulb must be placed under the top, a little aside from the hole where the shaft of the motor pierces the top of your cabinet, in order to emit an even and steady light under the revolving discs. Put your bulb in connection with batteries and your outfit is complete. In order to multiply its charming effects it is advisable to place it in a very dark place. Now, when the switch is thrown, the motor begins to revolve very rapidly, at many thousand revolutions per minute, so that the discs flying around emit charming and various bright colors, owing to the bulb underneath, and when placed in some dark corner of a store window at night it will run for hours, its beautiful effects proving a sure attraction.

RAIN TO ORDER.

The artificial production of rain is about to be put to the test of practice in Australia. According to the *Electrician,* London, experiments are to be carried out by J. G. Balsillie, who has for four years been conducting researches into these possibilities. A captive balloon at a height of 6,000 or 7,000 feet will be used to discharge electricity in two forms to the atmosphere. This, it is hoped, will cause sufficient ionization to provide nuclei upon which the moisture of the clouds may condense. Mr. Balsillie believes that a number of these stations set up in the path of the prevailing winds would draw all the moisture from the clouds carried by them.

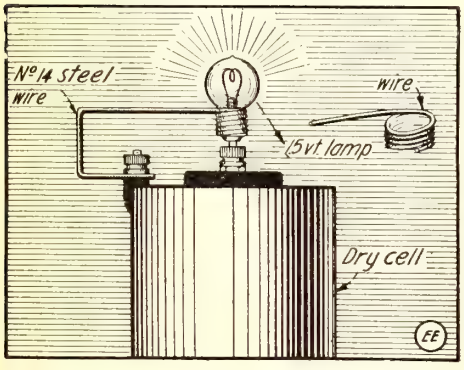
HOW TO MAKE IT



This department will award the following monthly prizes: FIRST PRIZE, $3.00; SECOND PRIZE, $2.00; THIRD PRIZE, $1.00.
The idea of this department is to accomplish new things with old apparatus or old material, and for the most useful, practical and original idea submitted to the Editors of this department, a monthly series of prizes will be awarded. For the best ideas submitted a prize of $3.00 will be given; for the second best idea a $2.00 prize, and for the third best a prize of $1.00. The article need not be very elaborate, and rough sketches are sufficient. We will make the mechanical drawings.

SECOND PRIZE $2.00.

A HOME-MADE BATTERY LAMP.

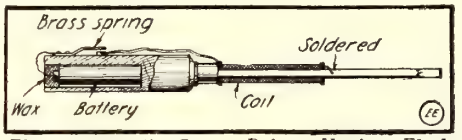
Bend one end of a 6-inch piece of No. 22 steel wire into a spiral large enough to allow a miniature lamp to be screwed into it. Do the same to the other end, only make the loop just large enough to slip over a zinc binding post on a dry cell. It is best to twist the ends. About 1½ inches from the large loop bend the wire at right angles. About ¼ inch from the smaller loop bend the wire so that it makes a square corner. Put the fixture on an ordinary dry cell. The bottom contact of the lamp should not quite touch the carbon binding post. By holding the battery in a horizontal position with the hand and by merely pressing on the wire the light will burn brightly. Although this design is simple it is quite efficacious.

Contributed by SHELBY BLONG.

Battery Lamp Holder and Switch Formed from Piece of Steel Wire. Beat It!

AN EMERGENCY FUSE PLUG.

While experimenting with the 110-volt house lighting current recently I accidentally blew out the fuse. As I had no extra ones on hand, and no time to go to town after another, I decided to make one the best way I could. Procuring an old burnt-out 16 candlepower carbon lamp I broke the bulb and removed all the pieces of glass from the base. I also took out the broken filament, which left the brass base with a small glass tube holding the two platinum wire supports. The ends of these supporting wires I cleaned with a file. I then carefully twisted the wires together and put a drop of solder on the joint.



After throwing open the switch I removed the regular fuse plug, containing the burnt-out fuse, and screwed my home-made fuse in, which I found to work excellently. It is obvious, however, that the switch should be open when inserting this makeshift fuse, as the brass base offers no insulation against a shock.

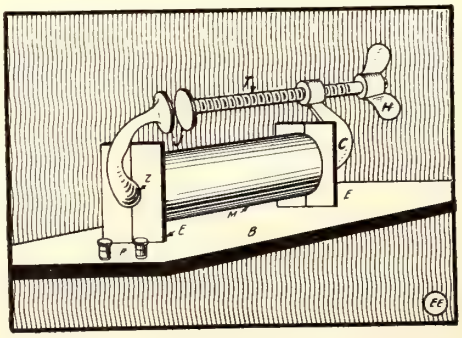
Contributed by MURIEL MURTAUGH.

FIRST PRIZE $3.00.

IMPROVED ELECTRO-MAGNETIC SCREW DRIVER.

Bore a hole into the handle of the screw driver the size of the cell used in a vest pocket flashlight battery. This hole will be about 3 inches deep by ⅝ inch in diameter. Solder a piece of fine wire to one pole of

Electro-magnetic Screw Driver Having Flash-light Battery in Handle.



the cell, and insert it into the handle far enough to come in contact with the inner end of the screw driver blade. Fill in the end with a wood plug and bring the end of wire through its center. With small brass screws fasten a thin brass strip to the handle and attach the wire to it. Then put another screw into the handle and attach a wire from the coil to it. The other end of the wire is soldered to the screw driver itself.

Having the battery in the handle of the tool will make it more useful and easier to carry than the one which was previously described in these columns, where the plan was to carry two or more standard dry cells with the screw driver, I believe.

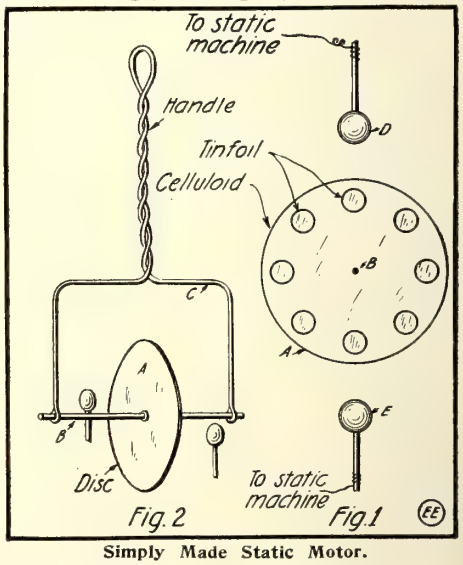
Contributed by C. A. SHEPHARD.

ADJUSTABLE MAGNETIZER MADE FROM WOOD CLAMP.

An ordinary furniture clamp of suitable size is fitted with two square wooden pieces, cut as at Z, in the figure. These pieces are placed around the shank of the clamp to serve as magnet ends. The split blocks are then joined with glue and allowed to dry. Wire of the proper size to obtain the desired magnet strength is next wound neatly between the ends E, E. The magnetizer is glued to a suitable base and is supplied with binding posts P. In using

An Adjustable Magnetizer Made from Iron Wood Clamp.

it the handle H is rotated until the desired distance is obtained.



Contributed by A. D. R. FRASER.

THIRD PRIZE $1.00.

A SIMPLE ELECTROSTATIC MOTOR.

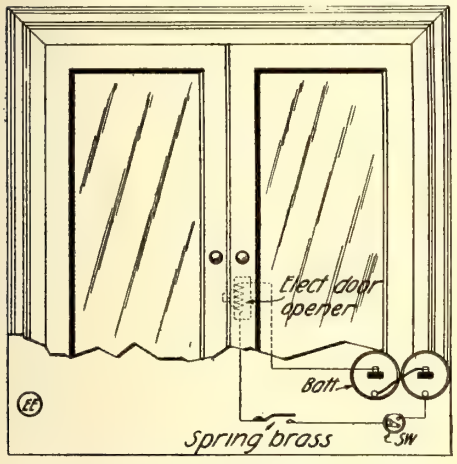
The little motor illustrated and described below is entertaining as a scientific toy and also serves to show how motion may result from an electrostatic field. It has the further advantage of costing practically nothing.

Fig. 1 shows the moving parts, which consists of a disc of stiff celluloid A, two inches in diameter. A large hatpin B (minus the head) is passed through the center and forms an axle, projecting an equal distance on either side of the disc. This may be secured with two little dabs of sealing wax, carefully applied. Eight small circles of tinfoil are stuck at equal distances near the edge, either gum, shellac, varnish

Simply Made Static Motor.

or celluloid cement being used as an adhesive. If the disc is suspended so as to be free to revolve, and brought between the discharging balls of a Wimshurst machine D and E, separated to a distance of about three inches, it will rotate at a considerable speed upon working the machine. Usually the motor starts at once, but the writer has found that it is sometimes necessary to start it with the finger if the tinfoil circles happen to be exactly in line with the electrodes.

A convenient form of support is shown in Fig. 2, where A represents the celluloid disc, B the steel axle and C a handle bent from a piece of thin copper wire. The two arms supporting the axle should be at least three inches long and as wide apart as the length of the axle admits. If preferred, a little stand may be made with a wooden base and two uprights, the height of the latter being adjusted to suit the Wimshurst machine with which the motor is to be used.



Contributed by H. I. GRAY.

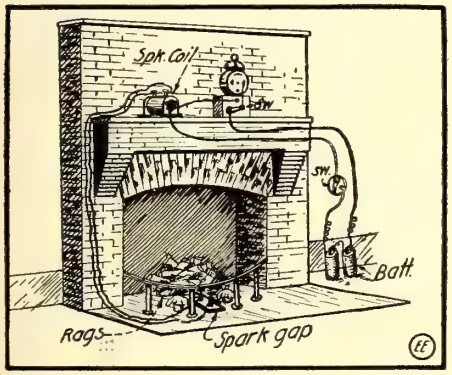
NOVEL USE OF DOOR OPENER.

Having frequently to go in the cellar and return with my arms full, I devised the following scheme whereby I can open the door without emptying my arms, although to a stranger the door is securely locked.

An electric door opener was put on the door and connected as an ordinary door opener, the only difference being that instead of going to a push button the wires led to a secret contact of spring brass, which was put in an out-of-the-way corner under the carpet.

When I wish to open the door I step on

Foot Operated Electric Door Opener.



the secret contact and the push-out spring opens the door.

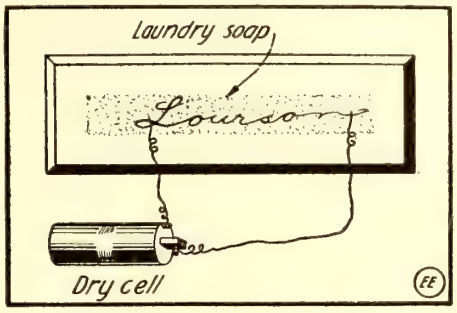
Contributed by CARL T. LUDWIG.

AN ELECRIC FIRE STARTER.

This electric fire starter prevents having to get up on a cold morning to start same.

All that is required is a spark coil of any size, enough batteries to operate the coil, an alarm clark, a battery switch, a box 8x3 inches, a tin pan, two cork stoppers and two needles. The stoppers are fastened to the bottom of the pan and the needles stuck through the corks, making a spark gap. The gap is connected to the coil and set under the grate. Some rags are bundled up tight and soaked in gasoline or turpentine and put just under the gap.

Alarm Clock and Spark Coil Start Fire in Morning. Spark Gap Should Be Protected With Asbestos to Prevent it Being Burned Up.



Over the rags are placed some splinters, and then wood and coal.

The alarm clock is wound and set and a loop put in a string over the alarm thumbscrew on the back of the clock. The other end is attached to a small switch coming from the batteries. The other wire from the batteries goes to the spark coil, and the opposite end of the switch connects to the coil. When the clock goes off, the thumbscrew will revolve, close the switch and start the coil. The spark will light the rags under the grate and start the fire.

Contributed by J. WESLEY BROWN, JR.

HOW TO DO ELECTRICAL ETCHING.

Following is a little experiment which

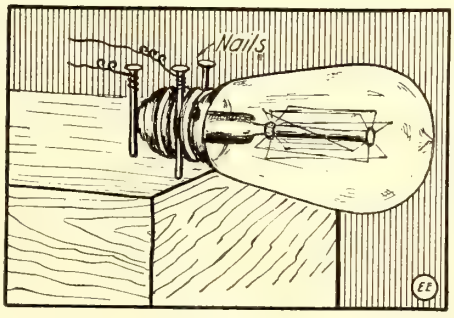
Simple Electric Etching Scheme.

can be successfully carried out by carefully following the directions herewith given. It will prove quite interesting, and will insure the object thus etched against theft, etc.

A few cents' worth of bluestone is procured and dissolved in one part of water, to which is added two tablespoonfuls of salt. Clean well the object to be etched. Next, with a piece of ordinary yellow laundry soap, coat the surface until a thin film of the same is applied. Then take a sharp-pointed pin and scrape, in one continuous path, the name or initials, etc., desired to be etched in and pour on the solution until the object to be etched is covered. The drawing explains at a glance the next step, and that is to connect a dry battery, with both wires from zinc and carbon in the solution. Leave thus for a few minutes.

Then rub off the soap with a rag, and the name, initial or whatever was scraped on the object, will appear. It is copper-coated and "etched in."

This little hint is invaluable for the laboratory or shop, where the owners of tools often lose, miss and hunt for their instrument. This mark is indelible and cannot be altered or taken out.



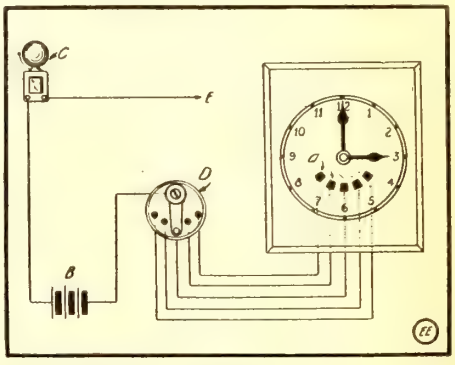
Contributed by WILLIAM WARNECKE, JR.

THE SIMPLEST LAMP SOCKET.

This emergency lamp socket is made in three seconds by driving two nails into the side of a piece of wood the right distance apart for the base of a lamp bulb to screw between, and one nail placed ¾ inch distant and at a point perpendicular to the other two.

A connection is made to one of the side nails and the other connection is made to the back nail. See cut.

Contributed by W. F. ALLSTON.



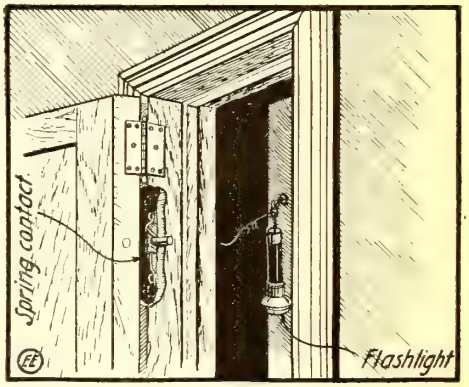
Simplest Lamp Socket. Made from Three Nails.

(If a lamp "socket" can be made of less material than the above we would like to see it!.—Ed.)

A PRACTICAL ELECTRIC ALARM CLOCK.

This is a rough but practical way in which to make a useful alarm clock.

At A are especially shaped brass or tin contacts. B is the battery, C a bell. D is the switch controlling the points on the clock. E is the wire which is to be connected to frame of clock, and completes the circuit when the hour hand strikes the metal points A. Caution: Let only the hour hand strike the contacts. The points will have to be adjusted so as to make the bell ring at the correct time, and of the proper height to allow the hand to pass over them after making contact. The



Useful Alarm Attachment for Any Clock. Switch Shown Permits Ringing Bell at Any Desired Time.

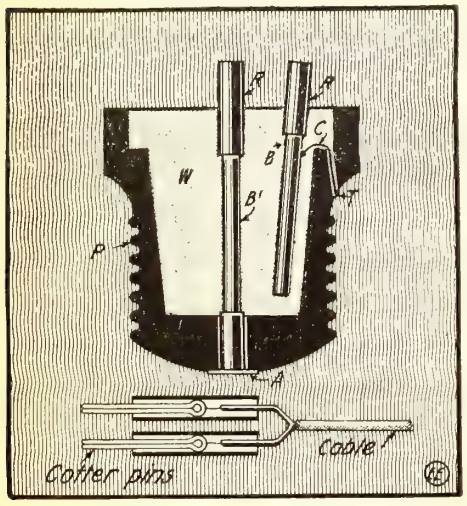
switch D may be placed in any convenient place. Another switch may also be put in series with the bell and placed close to the bed to facilitate the turning off of the bell without getting up. This switch should remain closed normally. I installed one of these clocks recently and it works very successfully. Contributed by

NORMAN W. BROWN.

FLASHLIGHT FOR ILLUMINATING DARK CLOSETS.

An ordinary flashlight can often be handily arranged so it will light a dark closet, wardrobe or pantry. It is supported on a hook or a nail inside of the closet, and a spring switch with extending rod, similar to a burglar alarm switch, may be placed on

Door-Controlled Spring Switch Used to Close Flashlight Circuit When Closet Door is Opened: Extinguishes It When Door is Closed.



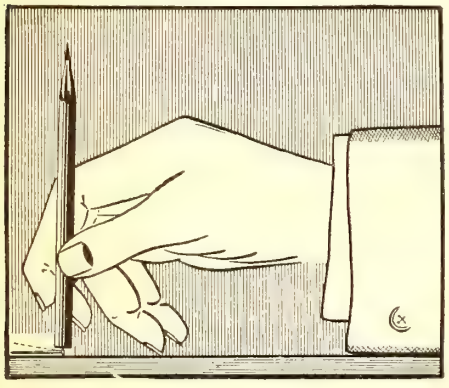
the door jamb. When the door is closed the spring will be separated and the light will be extinguished, but when the door is opened the spring switch closes, lighting the closet or pantry, as the case may be. Ordinary bell wire will be found suitable for making connections between the switch and the flashlight. This form of illumination will be found efficacious in solving many other lighting problems of a similar nature.

Contributed by B. J. SARTER.

USEFUL ATTACHMENT PLUG.

This plug may be made from an old plug type fuse with the brass top removed. The thread and one brass tube should be connected by a wire through the channel usually found on such plugs. To connect wires to this plug, cotter pins of suitable size should be employed. The accompanying sketch depicts the different parts of the plug.

At P is an old fuse plug; B¹, brass tube soldered to contact rivet A; B, brass tube with wire from thread of "plug" soldered to it; C, connecting wire; T, connecting



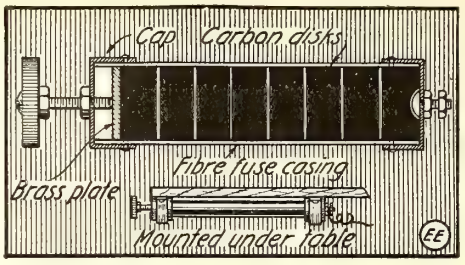
Separable Attachment Plug Made Out of Old Fuse Plug.

wire soldered to thread; R R, rubber tube to insulate B¹ and B; W, sealing wax.

Contributed by A. D. R. FRASER.

MORSE SOUNDER FROM A "PIN."

As a reader of your interesting review I beg to enclose the sketch of an idea of mine which up to the present I believe is not known, and perhaps it may be of interest to students of the Morse code. Place the bottom part of a pencil on the head of a small pin (on a table or other hard surface) and move the pencil, as shown in diagram, which will actuate as a sounder



A "Pin" Sounder That Works! Try It.

for practising the Morse code. Contributed by ANTONIO CORNISH-BESA,
Valparaiso, Chile.

A CARBON RHEOSTAT IN A CARTRIDGE FUSE SHELL.

Carbon rheostats are slowly but surely finding their place in the electrical field. Working on the principle of imperfect contact, they have the fine adjustment of a water rheostat without the attendant gases, while they are as easy to handle as a metal resistance and will carry a heavier current than a wire rheostat of the same weight, besides being very compact.

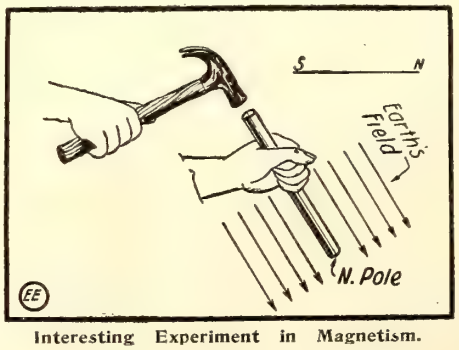
They can be made cheaply and in any size for your needs, but I will limit my description to a small one suitable for use in charging storage batteries, controlling small motors, or as a ballast for a small arc lamp.

Rheostat Composed of Carbon Discs in Fuse Shell.

Obtain a blown fuse cartridge shell whose internal diameter is the same as the diameter of the round carbon rods you should procure from some old, dry cells. Remove one fuse cap, take out the fireproof filling and any wires remaining at the ends.

Now take the carbon rod and carefully cut it up into ¼-inch lengths. The cuts should be straight across, so the discs will lay close together inside the tube. These discs are piled on top of one another till the tube is nearly full.

Connections are made to the two caps, one of which has an adjusting screw threaded through it to enable the operator to regulate the pressure between the discs.



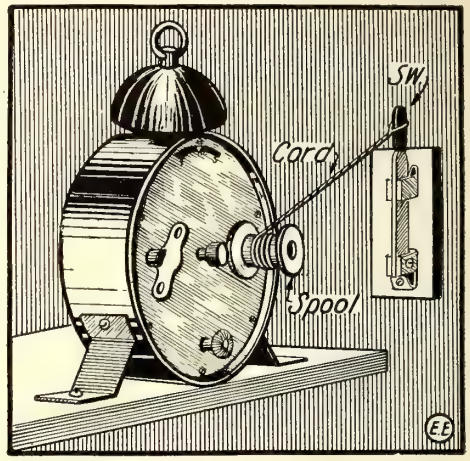
The sketch makes a lengthy explanation unnecessary, but it is advisable to use the system of mounting suggested, as otherwise when pressure would be applied by turning the knob the caps would be forced off the end of the fiber tube.

Contributed by
THOS. W. HANSON.

CURIOUS EXPERIMENT IN MAGNETISM.

One of the simplest yet most puzzling experiments in magnetism can be performed with a rod of machine steel held in the earth's magnet field. It is well known that it is difficult to free iron completely of magnetism. That is, it is almost impossible to completely demagnetize it. For this experiment a piece of very soft machine steel is desirable.

If a small compass is brought near one end, the North seeking pole will be found to be either attracted or repelled. At the other end the reverse condition will be obtained. Hold the rod of iron in the earth's field, whose general direction is North and South, and strike one end with a hammer, as perceived from illustration. The end of the rod which is pointed North will become a North magnetic pole. If the rod is reversed and a blow struck on the end with the hammer, the magnetism in the rod will be found reversed. This is tested for by means of a compass needle.

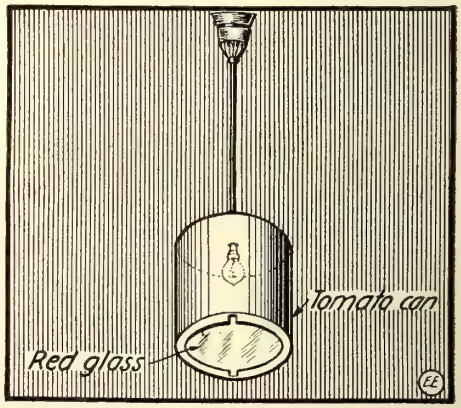


Interesting Experiment in Magnetism.

As the earth's field is not parallel with the surface of the earth, better results will be obtained if the rod is pointed toward the earth, at an angle of say 60 degs., care being taken to keep the rod in a general North and South direction.

NOVEL ELECTRIC TIME SWITCH.

First procure an alarm clock. Take the winding key off the alarm pinion shaft and fasten a spool to it by means of a brass bushing. Next obtain a common knife switch. Arrange the clock and switch as



Alarm Clock Opens Switch at Any Desired Time.

shown in sketch. Fasten the cord to the switch and then close it; next wind the alarm and fasten the other end of the cord to the spool. Wind the alarm and set at the desired time for turning off the switch, and when the alarm goes off the switch will be pulled open. This switch has been used with much success on store window lights.

RED LIGHT FOR PHOTO DEVELOPING ROOM.

A tomato can when opened leaves a rim

Ruby Lamp Made Out of Tomato Can.

about ⅜ inch wide. Flatten this rim and cut out notches for passing a red glass disc through. Put a hole in center of the top cover for wire to incandescent light, as shown in drawing.

Contributed by
NICHOLAS ACCARDI.

Connect a Geissler tube across your primary leads. It will protect the set from heavy static surges and lightning. You can't expect to make a good joint by merely twisting the wires—solder them.

Under this heading we will publish every month useful information in Mechanics, Electricity and Chemistry. We shall be pleased, of course, to have our readers send us any recipes, formulas, wrinkles, new ideas, etc., useful to the experimenter, which will be duly paid for, upon publication, if acceptable.

FORMULA NO. 18.

Solders.

1. *Plumbers' Solder.—Lead,* 2 parts; *Tin,* 1 part.

2. *Tinmen's Solder.—Lead,* 1 part; *Tin,* 1 part.

3. *Zinc Solder.—Tin,* 1 part; *Lead,* 1 to 2 parts.

4. *Spelter Solder.*—Equal parts *Copper* and *Zinc.*

5. *Glazier's Solder.—Tin,* 3 parts; *Lead,* 1 part.

6. *Solder for Copper.—Copper,* 10 parts; *Zinc,* 9 parts.

7. *Brass Solder.—Copper,* 61.25 parts; *Zinc,* 38.75 parts.

8. *Brass Solder, White.—Copper,* 57.41 parts; *Tin,* 14.60 parts; *Zinc,* 27.99 parts.

9. *Black Solder.—Copper,* 2 parts, *Zinc,* 3 parts; *Tin,* 2 parts.

10. *Cold Brazing Without Fire or Lamp. —Fluoric Acid,* 1 oz.; *Oxy-muriatic Acid,* 1 oz.; mix in a lead bottle. Put a chalk mark each side where you want to braze. This mixture will keep about six months in one bottle.

11. *To Solder Iron to Steel or Either to Brass.—Tin,* 3 parts; *Copper,* 39½ parts; *Zinc,* 7½ parts. When applied in a molten state it will firmly unite metals first named to each other.

12. *Plumbers' Solder.—Bismuth,* 1 part; *Lead,* 5 parts; *Tin,* 3 parts; is a first-class composition.

13. *Solder for Brass That Will Stand Hammering.—Brass,* 78.26 parts; *Zinc,* 17.41 parts; *Silver,* 4.33 parts; add a little chloride of potassium to your borax for a flux.

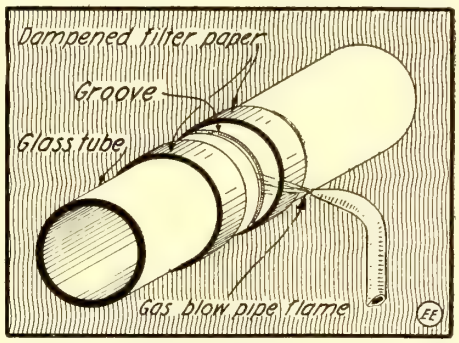
14. *Solder for Steel Joints.—Silver,* 19 parts; *Copper,* 1 part; *Brass,* 2 parts. Melt all together.

15. *Hard Solder.—Copper,* 2 parts; *Zinc,* 1 part. Melt together.

16. *Solder for Brass.—Copper,* 3 parts; *Zinc,* 1 part; with *Borax.*

17. *Solder for Copper.—Brass,* 6 parts; *Zinc,* 1 part; *Tin,* 1 part; melt all together well and pour out to cool.

18. *Solder for Iron.*—The best solder for iron is good tough brass with a little borax.



N. B.—In soldering, the surfaces to be joined are made perfectly clean and smooth, and then covered with sal-ammoniac, resin or other flux, the solder is then applied, being melted on and smoothed over by a tinned soldering iron.

Soldering Fluid.—Take 2 oz. *Muriatic Acid;* add *Zinc* till bubbles cease to rise; add ½ teaspoonful of *Sal-Ammoniac.*

S. G.

HOW TO CUT GLASS TUBING.

To many, or rather most experimenters, it is a difficult thing to cut glass tubing larger than a half inch in diameter. Sizes under this can be broken after being cut or nicked slightly with a file. The method I will explain is that used in most chemical laboratories. To illustrate, say the tube is about an inch and a half or so in diameter. The required length of tubing is measured off and then a groove is cut around the tube with the corner of a file. This must be rather deep. Then a piece of filter paper is folded so as to be about two inches wide and long enough to go around the tube. The paper is then moistened. This and a similar piece are placed one on each side of the groove, leaving about a quarter of an inch between the two. A flame from a bunsen burner or blow pipe is then applied to the groove and it will be found that the tube breaks evenly along the file cut. Another method that can be used on smaller tubing, about half inch in diameter, is to make a cut as described and then apply a red hot piece of iron to one spot on the cut.

Easy Way to Cut Glass Tubing.

(A very simple method to accomplish the above is the following: Take a thick piece of string and soak it well in alcohol. Tie it around the part where tube is to be cut. Now light the string. The second it extinguishes dash a drop of cold water on it. A sharp, even break of the tube is the result. We have thus "cut" off the necks of large bottles.—*Editor.*)

Contributed by SYBEREN NYDAM.

CEMENTING GLASS TO METALS.

(1) A cement of great adhesive property, particularly serviceable in attaching the brass mountings on glass lamps, as it is unaffected by petroleum, may be prepared by boiling 3 parts of rosin with 1 part of caustic soda and 5 parts of water, thus making a kind of soap which is mixed with one-half of its weight of plaster of Paris. Zinc white, white lead, or precipitated chalk may be used instead of the plaster, but when they are used the cement will be longer in hardening.

(2) A cement for such purposes as fixing metal letters to glass windows consists of copal varnish 15 parts, drying oil 5 parts, turpentine 3 parts, oil of turpentine 2 parts, liquefied marine glue 5 parts. Melt in a water bath and add 10 parts dry slaked lime.

(3) Brass letters may be securely fastened on glass windows by the following recipes: Litharge 2 parts, white lead 1 part, boiled linseed oil 3 parts, gum copal 1 part. Mixed just before using this forms a quick drying and secure cement.

(4) One pound of shellac dissolved in a pint of strong methylated spirit, to which is to be added 1-20 part of a solution of india rubber in carbon bisulphide.

(5) Take 2 ozs. of a thick solution of glue and mix with 1 oz. of linseed oil varnish, or ¾ oz. of Venice turpentine. Boil together, agitating until the mixture becomes as intimate as possible. The pieces cemented should be fastened together for a space of 48 to 60 hours.

(6) One of the best cements for uniting glass to other substances is prepared by putting the best and purest gum arabic into a small quantity of water and leaving it till next day, when it should be of the consistency of treacle. Calomel (mercurous chloride or subchloride of mercury) is then added in suitable quantity, enough to make a sticky mass being well mixed on a glass plate with a spatula. No more is to be made than that required for immediate use. The cement hardens in a few hours, but it is wiser to leave it for a day or two. To insure success it is necessary to use only the very best gum; inferior sorts are absolutely useless.

(7) Before glass can be soldered to metal it must be "quicked" upon the side that is to be soldered. The "quicking" process is similar to, if not identical with, the method of silvering a looking glass. When the glass is "quicked" it may be readily soldered to the metal, using Venice turpentine or chloride of zinc as a flux.

(8) Sixty parts starch, 100 finely pulverized chalk are made into a mixture with equal parts of water and spirit, and the addition of 30 parts Venice turpentine, taking care to agitate the mass with a stick, so as to insure its homogeneity.

(9) Four parts glue melted with the least possible quantity of water, 1 part Venice turpentine will resist moisture.

(10) That solder in some form adheres to glass is well known and practised by the makers of fictitious jewelry. These are made up of pieces of black glass, cut and polished, and fairly soldered on to metal plates. By breaking one of these across it will at once be seen how strong the adherence really is. If the work has been well done the pieces of glass do not fly off, but are difficult to remove except in fragments. This soldering is done as follows: The shields, or metal plates, are coated with a thick layer of tin; these, together with the appropriate pieces of glass, are laid on an iron plate, heated to the melting point of the tin. The piece of hot glass to be soldered is then picked up with forceps and its edge introduced under the surface of the melted stratum of tin and slid forward so as to carry some of the metal before it, thus skimming off the oxidized surface so as to bring clean glass and clean metal in absolute contact. No glue must be used; the least trace of oil or resin will spoil the operation. When the piece of glass is fairly in place it is pressed down in order to squeeze out the surplus solder. It is this sliding action that insures success; if the glass were to be directly pressed down upon the tin solder no adhesion would take place at all from the presence of a trace of oxide and the existence of an air film. The glass, of course, must be polished and perfectly clean.

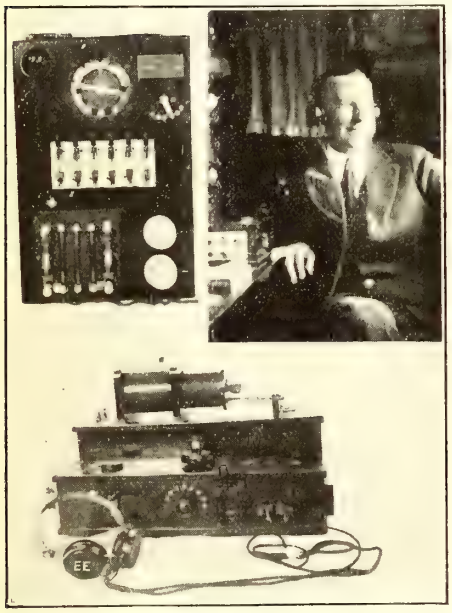
(11) Beeswax and Venetian turpentine in varying proportions, depending upon consistency desired.

Leather Preservatives.—One hundred parts *Sweet Oil,* 100 parts *Mutton Suet,* 2 parts *Turpentine.* Melt together and apply to the leather, which has been sufficiently warmed so that it will liquefy and absorb the fat. Another formula is as follows: 10 oz. *Linseed Oil,* 10 oz. *Mutton Fat,* 1 oz. *Venice Turpentine* melted together. Apply to the leather when dry and warm and it will preserve it against wet or snow.

WITH THE AMATEURS

Our Amateur Radio Station Contest is open to all readers, whether subscribers or not. The photos are judged for best arrangement and efficiency of the apparatus. To increase the interest of this department we make it a rule not to publish photos of stations unaccompanied by that of the owner. Dark photos preferred to light toned ones. We pay each month $3.00 prize for the best photo. Make your description brief. Address the Editor.

AMATEUR RADIO STATION CONTEST.



Monthly Prize, $3.00.

This month's prize winner.

THE HOPKINS RADIO STATION.

The accompanying views show the apparatus employed in my successful radio station. The receiving set is of the cabinet style, which consists of a loading coil, loose coupler, primary and secondary variable condensers, crystaloi detector, fixed condenser and a pair of 2,000-ohm 'phones. With this set I am able to hear nearly all the coast stations from (N. A. R.) Key West to (W. C. C.) South Wellfleet.

The transmitting set is of the rotary panel type, which is highly efficient owing to the very short connections. In the base is mounted a ½-K. W. closed core transformer, and above that is the adjustable condenser and rotary spark gap. At the rear of this is the oscillation transformer.

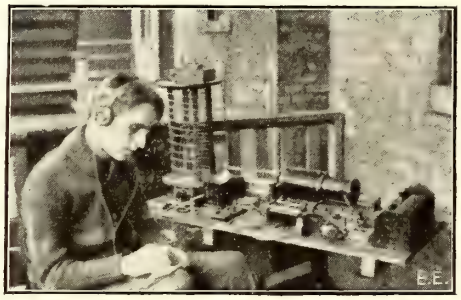
James R. Hopkins and Wireless Set Built by Himself.

The photo shows protective device, condenser and rotary controlling switches mounted on the fiber panel. I am able to communicate with amateurs and ships within a radius of 50 miles and more.

The aerial consists of two copper wires 82 feet long and 35 feet high.

JAMES R. HOPKINS.

Newport News, Va.



C. JAROSZEWICZ'S WIRELESS OUTFIT.

Herewith are photographs and description of my wireless set for the Amateur Wireless Station contest.

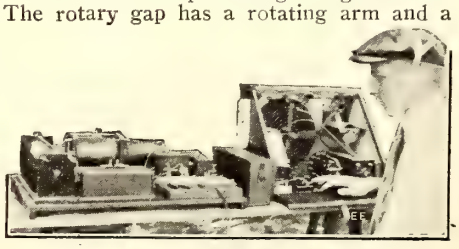
The aerial is 75 feet high and 80 feet long and is composed of six strands of No. 12 hard-drawn copper wire.

The set is all home-made with the exception of the receivers and spark coil.

My receiving set consists of 2,000 ohm Brandes' 'phones, loose coupler, two-slide tuner, loading coil, galena, silicon, ferron, carborundum, and copper-iron pyrites detectors, variable condenser and fixed con-

Fine Experimental Radio Station of Mr. Jaroszewicz.

denser. On favorable nights I can hear N.A.A. 10 feet from the 'phones, while W.G.O. can be heard 50 feet from the 'phones.



My transmitting set comprises a Mesco type, two-inch spark coil, spark gap, condenser, helix and key. For the source of current for operating the spark coil I use a dynamo which I have constructed with the help of my father. This dynamo while running at a speed of 2,800 r. p. m. generates 50 volts and 30 amperes. The armature of this dynamo is wound with insulated copper ribbon.

Chicago, Ill. CASIMIR JAROSZEWICZ.

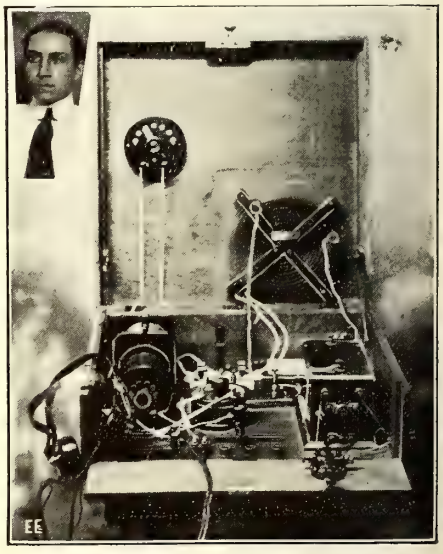
UNIQUE RADIO OUTFIT OF FRANK SAHLMANN.

The following is an explanation of my little wireless set, a picture of which is herewith presented.

The set was all made by myself, with the exception of the jump spark coil and the step-down transformer. The key has large platinum points taken from an old spark coil vibrator. The oscillation transformer is made of brass ribbon which has been split and wound on cross arms in the shape observed. The sending condenser was constructed from an old glass tumbler with thin walls, coated inside and outside with tinfoil. The spark gap was made from an old telephone lightning arrester. The rotary gap has a rotating arm and a

Frank Sahlmann's Radio Apparatus.

stationary disk, which renders the gap easier started and stopped and also reduces the vibration. The small rheostat shown is used to regulate the current feeding the coil and is made up of old screen wire.



In the receiving set the fixed-adjustable condenser is made up of eight small units, containing from two to 16 sheets of tinfoil each and so connected that from two to 30 sheets may be used at one time. The wire used on the loading coil and the tuning transformer was obtained from the regulating coil of an old arc lamp. The bell and the battery are used for testing purposes. I have made a cover for the receiving set which is not shown. It will be noticed that the set is very compact and thus easily carried from place to place.

Salina, Kan. FRANK SAHLMANN.

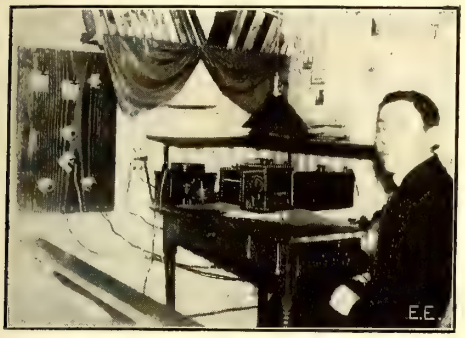
D. J. CYR'S WIRELESS STATION.

The accompanying illustration is that of a portable wireless outfit mounted in a specially designed, quarter-sawed oak case made by the owner.

The outfit consists of, from left to right: a loose coupler, a fixed condenser is placed alongside of it; a 23-plate variable con-

Portable Radio Set of Darrel J. Cyr.

denser, a three-cup detector (the bracket being on a rod so as to slide to the different minerals, which are galena, silicon and molybdenite), spark gap, 1-inch spark coil and a moulded sending condenser back of it. The key is on the hinged front and the helix is fastened on the cover. The switch is seen in the rear center. One 1,000-ohm headset is shown in the picture, but will be replaced by 3,000-ohm 'phones. A 5,000-meter loading coil has been placed in the cabinet.



My aerial consists of six wires, spaced 18 inches apart, in the shape of a "V." It is hung on 18-foot poles on top of a house 35 feet high. I can get NAA, WSL and other stations.

I am a member of the Central Radio Association and the National Amateur Wireless Association.

Sioux City, Iowa. DARREL J. CYR.

JOEL YOUNG'S WIRELESS STATION.

My set consists of two receiving outfits—one containing a loose coupler, an audion detector and a mineral detector, one variable condenser, one pair of Murdock receivers of 2,000 ohms resistance; while the other is a new set. This consists of a tuner, one variable condenser and one pair of Murdock 'phones. The outfit is capable of

Joel Young's Radio Station.

receiving Sayville and other undamped wave stations. I have the audion arranged with a double-pole, double-throw switch, so that I may use it on either set. The audion terminals for the tuner go to the main poles of the switch and the secondaries of the other to the other end of the switch. The aerial and ground switches are worked in the same way.

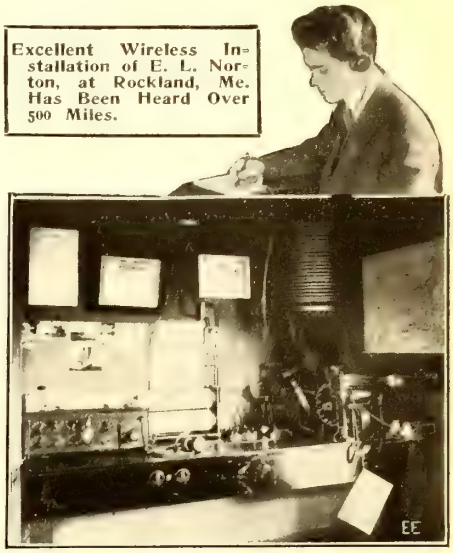
I can hear Arlington on both sets of instruments very loudly. I also hear amateur stations, and commercial ship and coast stations.

My sending set consists of a Blitzen one-quarter kilowatt transformer, a rotary spark gap of my own construction, besides a helix and condenser, both made by myself.

The sending outfit is controlled by a switchboard, which may be seen in the picture.

The sending apparatus is in a small building located about 60 feet from the house. The receiving outfit is in my room. Thus I operate the sending set at a distance of 60 feet, after the fashion of the large commercial stations.

My aerials are as follows: One has four wires, space l 2¾ feet apart, and is 30 feet high and 100 feet long. The other is 500 feet long, 35 feet high and contains but one wire. The material used is galvanized iron wire. The former is used for sending, and both are used for receiving. My official call is 8 ALK. JOEL YOUNG.



Elmira, N. Y.

RADIO STATION OF E. L. NORTON.

My radio transmitter consists of an .8-K. W. 10,000-volt transformer, rotary gap giving about 900 sparks per second, a condenser of .0085 mfd. capacity, an oscillation transformer and aerial loading inductance. The set is licensed to use all waves up to and including 600 meters. It has a normal night range of about 250 miles, but has been heard at a distance of over 500 miles *over land.*

The receptor is connected on the Armstrong oscillating audion system. With proper primary loading coils it will tune to 12,000 meters. The switches on the front of the cabinet from left to right are: Primary and secondary of large tuner, four switches for controlling the large coils used in the Armstrong system, the audion bulb, the high voltage battery switch, a telephone switch for lighting the audion bulb, changing over to the crystal detector if desired, or for shorting the latter while sending, and at the right a "Blitzen" tuner for short waves.

Excellent Wireless Installation of E. L. Norton, at Rockland, Me. Has Been Heard Over 500 Miles.

Two aerials are used, one for transmitting and for receiving on all short waves, which consists of six copper wires, 60 feet high and 76 feet long, and a single wire 325 feet long for all long waves.

EDWARD L. NORTON.

Rockland, Me.

Amateur News

Institute of Radio Engineers' December Meeting.

The December meeting of the Institute was held Wednesday evening, Dec. 1 in Fayerweather Hall, Columbia University, New York.

Two papers on "Capacities" and "Radio Transmission Phenomena" were presented by Fritz Lowenstein.

The first of these papers dealt with a number of interesting points in connection with the field energy of capacities and endeavored to correct certain common errors in connection therewith.

The second paper considered the phenomena of radiation from normal antennae and contrasted critically the explanation of these phenomena given by Tesla, with those at present in vogue. Highly novel and suggestive explanations of radio transmission were given.

Talo Club of New York City.

The Technical Association of Licensed Operators or Talo Club was formed on Oct. 21, 1913, with the purpose of gaining further knowledge of wireless by combining serious work with theoretical argument.

Meetings are held fortnightly at which papers are presented and discussed. The present membership is: W. Woodrow, president; E. T. Dickey, secretary and treasurer; W. J. Howell, past-president; W. H. Sands, F. L. McLaughlin, R. B. Austrian, S. A. Murray and M. W. Sterns. Address all communications to the secretary's office, 1649 Amsterdam Ave., New York City.

The Yorkville, N. Y., Radio Development Association.

Recently a radio club was organized by several amateurs and scientists who had "fallen" for the "tick-tick." An election was held and Mr. Joseph L. Cermak, was elected president. A very able vice-president was found in the person of Dr. Frank G. Josephs of New York City, also. The club was organized for the purpose of bringing to a higher state of perfection the telephonological radiocommunicative apparatus of the present time, and, according to the latest reports, everything is going along smoothly. Mr. Cermak, who is a hopeless "radio-bug," has contributed largely to the wireless field. An interesting series of wireless lectures were once given by him in Public School No. 158, Manhattan. The members at present consist of his able assistant, Frederick ("Sulphate") Smith, G. Engler, E.E., M.A.; Geo. Barry, Charles Lucek, Frank Bartinek and the honorable scribe, H. Gutman. All communications should be sent to Jos. L. Cermak, E.E., 73 East End Ave., New York, and a good-natured answer will be received by the next mail. Get busy, fellow "bugs."

New California Radio Club, at Redlands.

The amateurs of Redlands, Cal., have recently organized a radio club. The name of the club is "The Radio Club of Redlands." The officers of the club are Ezra Moore, president; Arthur Munzie, vice-president; Rudolph Kubias, secretary-treasurer; Harry Williamson, assistant secretary-treasurer. The other members of the club are Howard Hamilton, Donald Anderson, Ernest Tubbs, Charles Dewith, Norman Peiffer, Dean Fowler and Phillip Murkett. We would be glad to communicate with other radio clubs. Address Rudolph Kubias, No. 457 Alta St., Redlands, Cal.

Radio Club of America October Meeting.

The October meeting of the Radio Club of America was held on Saturday evening, Oct. 9, in Room 304, Fayerweather Hall, Columbia University, New York City.

Mr. Fritz Lowenstein presented a paper on "Quenched Spark Sets." Mr. Lowenstein, who is well-known as a pioneer in this field of apparatus development, described in detail the principles, design and operation of sets of this type, discussing critically many recent developments in the general theory of transmission as applied to quenched spark apparatus.

John L. Hogan, Jr., Emil J. Simon, M. E. Packman and G. J. Eltz were the chief participants in the discussion.

RADIO CLUBS ATTENTION!

We are always pleased to hear from young Edisons and Radio Clubs. Send a write-up of your Club with photos of members and apparatus to-day to: Editor "Amateur Gossip" Section, The Electrical Experimenter, 233 Fulton St., New York City.

East Night High School Radio Society.

On the evening of Oct. 7, the students of the East Night High School of Cincinnati O., interested in the radio art were organized by Mr. Wm. G. Finch and Mr. C. H. Fender, pioneer radio men. The organization was named the East Night High School Radio Society, whose objects are as follows: 1—Advancement and development of the "Radio Art"; 2—To prepare the members to qualify for U. S. Government commercial operator's license; 3—To be able to render effective assistance during times of emergency; 4—To promote radio intercourse among other institutions of learning in the United States.

The following officers were elected: President, Wm. G. Finch; Secretary, C. H. Fender; Treasurer, Professor Frantz.

The society at present has a membership of fifty-two. The society will install a 5 K.W. transmitting set of the most modern type; the receiving set to be the last word in radio engineering. The organization extends an invitation to all other institutions of learning which are in sympathy with their movement to effect a "relay association" among them. Those who are interested in the above movement please communicate with C. H. Fender, secretary, East Night High School Radio Society, Cincinnati, Ohio.

The Junior American Guard.

Boys are wanted to join the Junior American Guard, a juvenile national guard, whose object is to instil into boys the proper regard for discipline, obedience and military instruction.

Among the activities to be carried on are military instruction and engineering, first aid, signaling, wireless telegraphy, marksmanship and drum, fife and bugle instruction.

Since its organization last May, its membership has reached 3,000. At the head of the organization is Brig.-Gen. Andrew C. Zabriskie, a 7th Regiment veteran, and former member of the Governor's staff, and who for many years has been connected with boys' activities.

Second in command is Maj. William H. Elliott, formerly with the Boy Scouts. Headquarters have been established at No. 52 Beaver St., New York City.

Chas. F. White, 117 East 127th St., New York City, wishes to hear from boys between 12 and 18 years of age, especially those interested in wireless telegraphy, for the purpose of organizing a radio and signal corps.

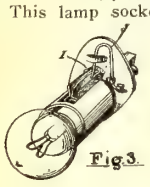
Information will be gladly furnished to anyone over this age who desires to organize in or outside of New York City.

LATEST PATENTS

Focusing Lamp Socket.

(No. 1,153,591; issued to William F. Anklam.)

This lamp socket is intended for



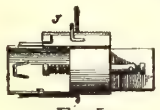


Fig.3.

Fig.4.

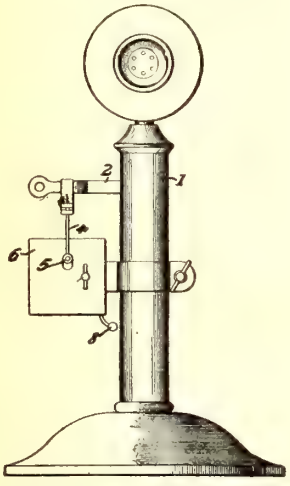

Fig.5.

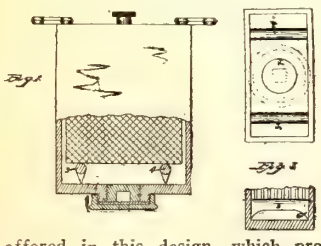
automobile head lamps where it is desirable and in many cases imperative, that the electric lamp itself shall be properly focused. The socket in this case is held in any required position by means of a flange, rack I and spring wire catch J, engaging same at any desired point to which it may be set.

Telephone Fire Alarm Attachment.

(No. 1,155,722; issued to Felix Gottschalk.)

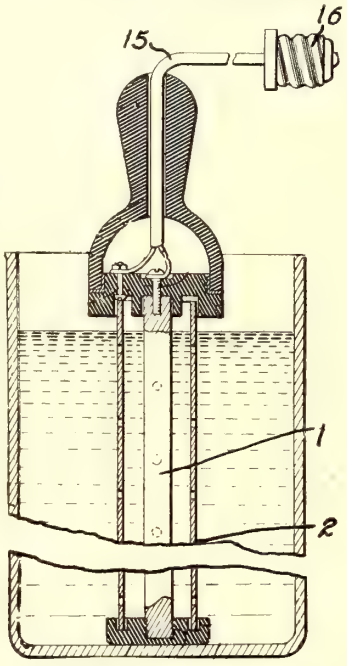


In this telephone fire alarm device, use is made of a fusible link which in case of fire, melts, thus releasing the switch hook 2, and also the trigger 5, of a clockwork actuated mechanism 6, containing a tapper 8. This strikes repeatedly by code signals or otherwise, against the metallic upright column of the telephone stand 1. These tapping sounds are heard at the central office exchange and it is then known exactly from what source the alarm emanates. This device here shown is for telephones other than the common battery type.

Easily Cleaned Storage Cell.

(No. 1,154,372; issued to Augustus P. Burritt.)

An improved storage cell jar is

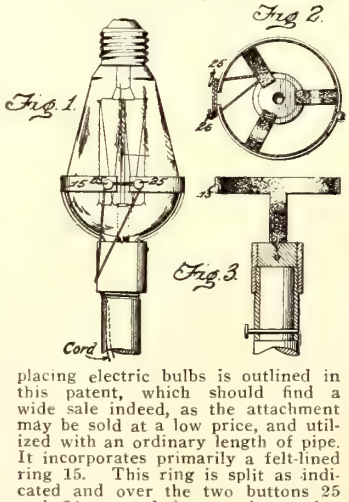


offered in this design, which provides at the bottom of same a large orifice with threaded cap, which may be opened periodically to facilitate the flushing out of the sediment, etc., from the cell. The plates are supported on the arched ribs 3 and 4, thus permitting of the solution or flushing water passing readily through them, without impeding the discharge of the sediment, etc., in this action.

Electric Water-Purifier.

(No. 1,159,699; issued to James A. Murdock, assignor of $\frac{7}{16}$ths to John H. Hirst, and $\frac{9}{32}$ds to Cecile A. Murdock.)

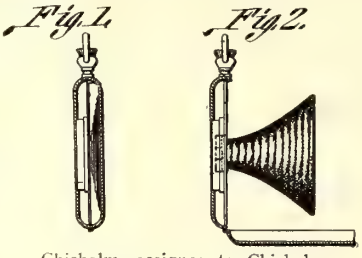
This scheme for purifying water



by the action of electrolysis is made possible by passing ordinary lighting current into a cell containing the liquid as shown in the illustration. The electrodes 1 and 2 are connected to opposite sides of the circuit through the medium of a flexible conductor and plug 15 and 16. The tubular electrode 2 is perforated, to enhance the circulation of the liquid.

Electric Globe Replacer.

(No. 1,157,617; issued to Elwood H. Conrad.)

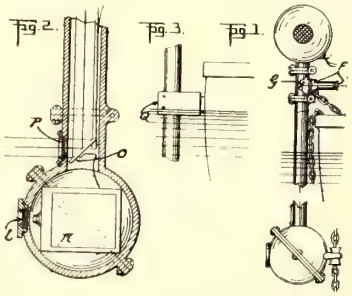


A simple and cheap method of re-

placing electric bulbs is outlined in this patent, which should find a wide sale indeed, as the attachment may be sold at a low price, and utilized with an ordinary length of pipe. It incorporates primarily a felt-lined ring 15. This ring is split as indicated and over the two buttons 25 and 26 a cord is passed, so that when a bulb is placed in a socket, the cord through the re-lamper handle is pulled taut; thereby causing the ring 16 to contract and grip the globe tightly.

Individual Telephone Mouth-Piece.

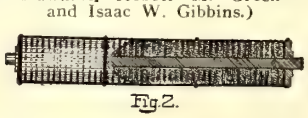
(No. 1,158,636; issued to Chas. L. Chisholm, assignor to Chisholm Transmitter & Telephone Instruments Company.)



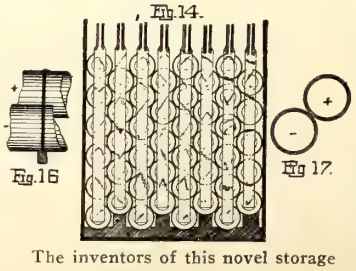
The patentee of this invention claims to provide a satisfactory and convenient form of collapsible and sanitary microphone mouth-piece for telephone systems. Great stress is laid on the unsanitary aspects of the common telephone mouth-piece and he here provides one which may be carried by every individual in the same way as a watch. The mouth-piece is collapsible and comprises a spiral wire form, supporting (when extended) a flexible covering material, such as soft rubber or oiled silk, etc.

Device for Under-Water Exploration.

(No. 1,156,782; issued to Charles Francis Jenkins.)



This device comprises a telescopic tube as illustrated, fitted with two chambers, at top and bottom. The

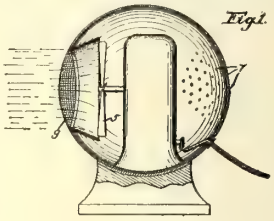


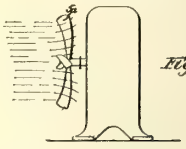
submerged, lower chamber contains a motion picture camera, electrically controlled by means of a wire passing down through the tube from the deck of a vessel or float. A powerful light is enclosed in the upper shell and is projected downward through the tubes, being reflected from a mirror O, through a window P. Pictures are taken by the camera M, through the window L. The submarine landscape may be viewed through a telescope F, by means of a small reflecting mirror G placed in focus of mirror O.

Improved Storage Battery.

(No. 1,159,021; issued to Harry S. Hawkins, Abbott M. Green and Isaac W. Gibbins.)

Fig.2.



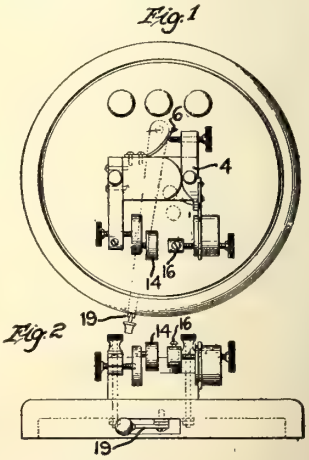


The inventors of this novel storage battery, which seems to possess considerable merit, have designed the positive and negative electrode or plates of a number of cylindrical rods. As may be seen from the illustration each of these rods is made up of alternate discs on a central, lead alloy bar. Every other disc is composed of an active material, which is oxide of lead, and the intermediate discs are made of a porous material, such as volcanic scoria. Around each compound cylinder thus constructed there is placed a foraminous sleeve, of lead alloy for instance, which is also perforated.

Electric Fan Motor.

(No. 1,156,901; issued to Chester I. Hall, assignor to Chicago Electric Meter Co.)

This is another form of electric



fan motor and is intended to be mounted with motor complete inside of a metal or other shell, as seen in illustration. This shell, at the rear of the fan, is perforated with numerous holes through which the air is drawn and the fan blade projects a draft of air through a screen 9; the mesh of which is not so fine as to impede the propagation of the air. The patentee also claims that by special construction of the blade 5, Fig. 1, and also at 5a, Fig. 2, particularly, that a practically parallel stream of air can be projected or produced.

Radio Detector.

(No. 1,159,969; issued to Charles O. Lorenz.)

This radio detector involves sev-

eral unique features and is to be used with minerals such as Perikon. The support 16 is mounted on a pivoted arm 4, resiliently by virtue of the spring 6. Hence the adjustments of the mineral cup 16 are made independent of the spring tension. The second mineral cup is shown at 14. A short-circuiting switch 19 is provided for protecting the detector while transmitting.

COPIES OF ANY OF THE ABOVE PATENTS SUPPLIED AT 10c. EACH.

Phoney Patents

Under this heading are published electrical or mechanical ideas which our clever inventors, for reasons best known to themselves, have as yet not patented. We furthermore call attention to our celebrated Phoney Patent Offizz for the relief of all suffering daffy inventors in this country as well as for the entire universe.

We are revolutionizing the Patent business and OFFER YOU THREE DOLLARS ($3.00) FOR THE BEST PATENT. If you take your Phoney Patent to Washington, they charge you $20.00 for the initial fee and then you haven't a smell of the Patent yet. After they have allowed the Patent, you must pay another $20.00 as a final fee. That's $40.00 ! ! WE PAY YOU $3.00 and grant you a Phoney Patent in the bargain, so you save $43.00 ! ! When sending in your Phoney Patent application, be sure that it is as daffy as a lovesick bat. The daffier, the better. Simple sketches and a short description will help our staff of Phoney Patent examiners to issue a Phoney Patent on your invention in a jiffy.

I. M. STEWED, PUSSYCATNIPSTOWN, HAR.
FELINEOLA

Patent Specifications Filed, Sandpapered and Polished

To Sufferers Throughout the Land:

Let it be known that I, I. M. Stewed, of Pussycatnipstown, in the State of Harmony, have perfected certain necessary and useful improvements on nature. By means of my Cat-Organ or Felineola it is possible to transform a town infected with nerve-racking nocturnal noises into a burg of melody. All this to be accomplished by the proper grouping and controlling of those aforesaid sleep disturbers into a whole harmonious unit capable of rendering orchestral pieces with a purity of note found in none of our so-called modern instruments of the musician's art.

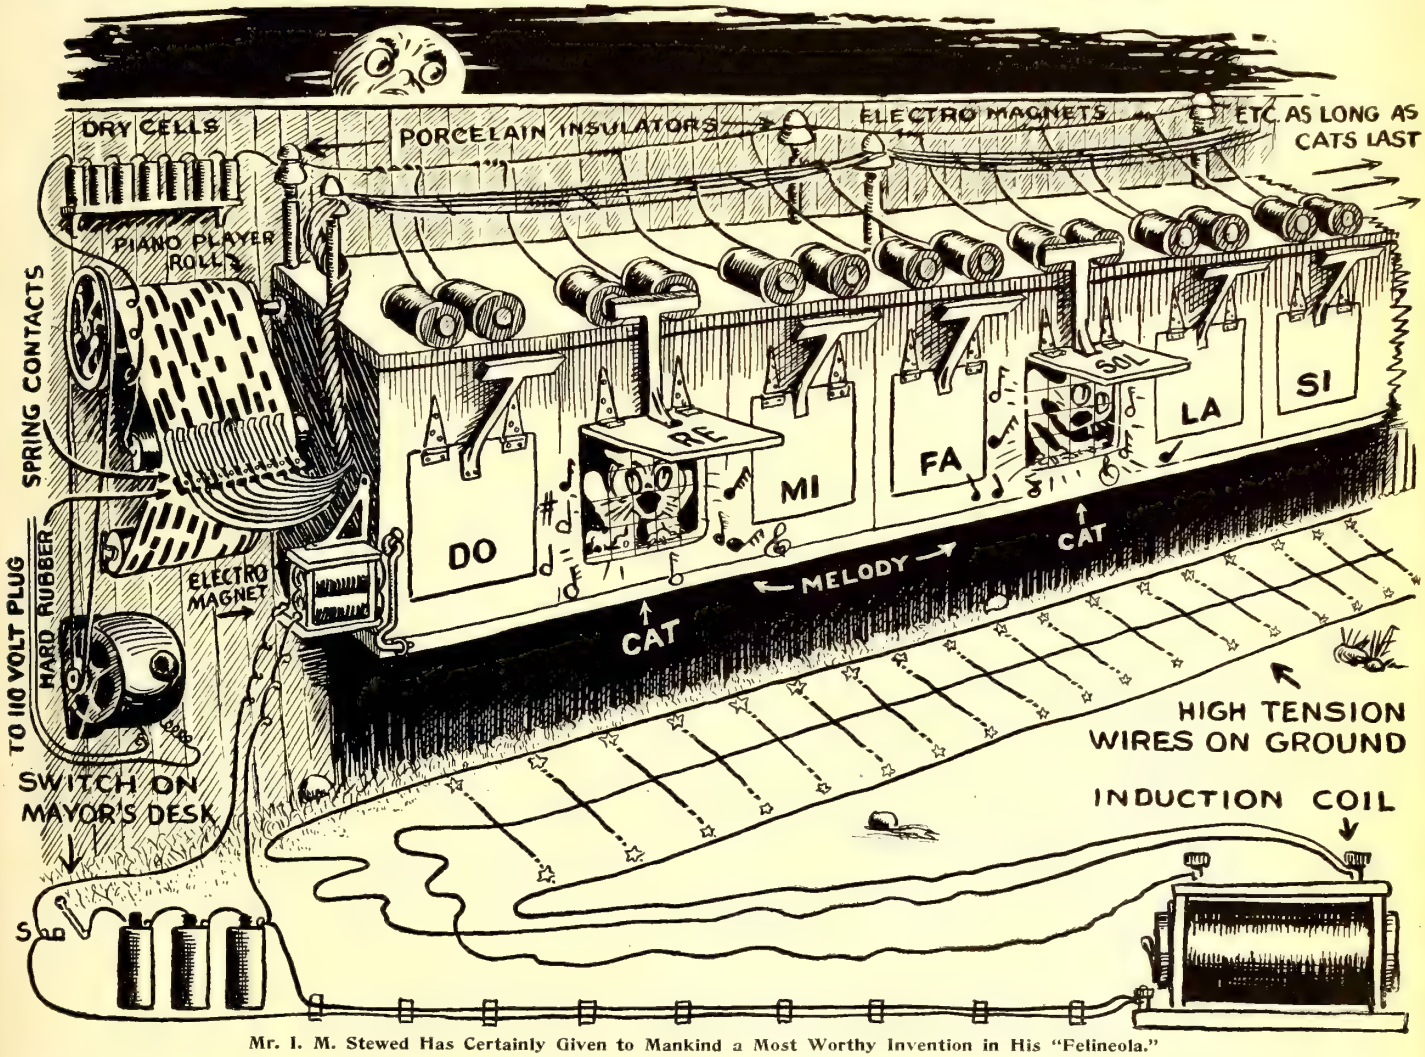
It consists primarily of a series of sound-proof receptacles, the openings of which are controlled by a keyboard. In each and every compartment is placed a cat as per specifications attached. The plan proposed also provides that each family in the neighborhood should dedicate a cat. They are graded according to the pitch of their voices (which does not correspond to their colors) and placed in the proper compartment.

Each box has a sound-proof door hinged at the top with an iron armature, attached so that the magnets on top will open the doors when energized.

The magnets are connected to electrical contacts, which are controlled by a regular player-piano roll driven by a motor.

The effect of this arrangement is the production of harmony that "hath powers to soothe the savage breast," and the screams of the felines will, to such craft as cruise in the neighborhood whose minds are distorted from the fumes of their alcohol burning furnaces, sound like the war cry of His Satanic Majesty, and they will at once deny all further allegiance to King Barleycorn. Thus not only will the citizens' tempers be saved but many erring souls will be saved from a life of degradation.

When the populace tires of this amusement, probably about 1.30 a. m., the Mayor has merely to close the switch and the bottom will drop out of the boxes and allow the cats to fall on the charged wires. They will disperse with one grand finale.



A method is also covered by my invention for recovering the cats for the next entertainment. The cats are, each and every mother's son of them, and daughter, too, fed with mush containing iron filings; after nine feedings they will become highly magnetic. Large electro-magnets mounted on the municipal fire truck will pick up the felines from the highways and low-ways to hold the concert.

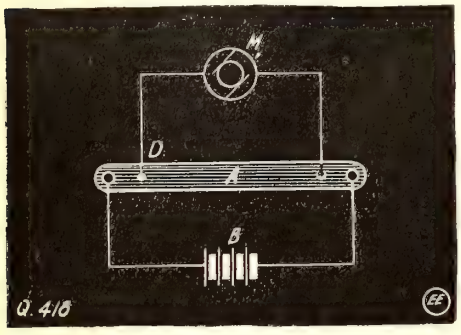
This metallic treatment will also give their voices a slight metallic ring that will make their serenade sound not unlike distant church bells on a Sunday morn.

In testimony thereof, I hereunto attach my seal as indication that this idea is approved by the S. P. C. A., for the cats will be no longer picked on or at by sundry bricks, books or alarm clocks.

I. M. STEWED,
Pussycatnipstown, Har.
By his attorney, R. L. Kunan,
Sabula, Iowa.

Witnesses:
WATT A. SIMP,
HOPE U. CHOKE,
TOM KATT.

Mr. I. M. Stewed Has Certainly Given to Mankind a Most Worthy Invention in His "Felineola."



QUESTION BOX

This department is for the sole benefit of the electrical experimenter. Questions will be answered here for the benefit of all, but only matter of sufficient interest will be published. Rules under which questions will be answered:

1. Only three questions can be submitted to be answered.
2. Only one side of sheet to be written on; matter must be typewritten or else written in ink, no penciled matter considered.
3. Sketches, diagrams, etc., must be on separate sheets. Questions addressed to this department cannot be answered by mail.

OHM'S LAW.

(418.) John T. Dwyer, West Philadelphia, Pa., sends us a drawing which is reproduced herewith and wishes to know if current can be drawn from points such as D on the bar A?

Operating Motor in Shunt to Bar Carrying Current.

A. Current may be drawn from the points mentioned, provided the resistance of the bar A between such points as D is equal to or greater than the resistance of the circuit through the motor M. The current flowing through this shunt circuit will depend on the ratio of these resistances.

AMPLIFYING HOOK-UP FOR DETECTORS.

(419.) C. R. White, Brooklyn, N. Y., writes us, asking for a method enabling him to use an audion to amplify from a Perikon detector.

A. We refer you to query No. 410, January, 1916, issue; this hook-up can be used with your instruments.

REGARDING SELENIUM.

(420.) Albert Walker, Erie, Pa., writes us for the address of a concern supplying selenium.

A. This peculiar material is handled by several concerns throughout the United States. The Electro Importing Co., 233 Fulton street, New York City, can supply you with this element in any quantity desired at a nominal price.

CALCULATING AREA OF CONDENSERS.

(421.) David Causey, Greenville, Ill., desires: 1. The formula for calculating the area of tinfoil and glass plates, used in the construction of a condenser for any given capacity. 2. The usual voltage and amperage of three-bar telephone magneto.

A. 1. The formula appended will enable you to calculate the area of the active dielectric necessary for any given capacity:

$$A = \frac{36 \text{ pi } d \times C \times 10^5}{K}.$$

In this formula d is the thickness of the dielectric in cms., C the capacity of the required condenser in M.F. The dielectric constant K can be obtained from any textbook on the subject, and the answer will be the area of the active dielectric in sq. cms. (also pi = 3.1416). The total area may be made up of any number of plates, but for high tension condenser construction the plates are usually 10x12 inches, while in small, low tension condensers the tinfoil strips are usually three inches wide, and the paraffine strips are four inches wide.

A. 2. The regular three-bar telephone magneto delivers about 75 volts and one-quarter ampere, alternating current.

LOADING COILS.

(422.) Grant Merrill, Redwood City, Cal., writes for information on the size of wire used in constructing tuning coils and the best method of making same, whether to wind the coil in a single layer or to wind it in many layers?

A. Loading coils as well as tuning coils can very well be wound with No. 24 to No. 26 magnet wire. The best way of making your loading coil is to wind it on a long cardboard tube in a single layer. Any kind of insulated wire may be used. The wave length is correctly figured by noting the inductance of the coil, which will have to be calculated from some one of the various formulas given in text-books. A simple rule for calculating the wave length of any tuning coil or loading coil is to multiply the length of wire in feet on the coil by 1.5, which will give approximately the wave length in meters.

STORAGE BATTERIES.

(423.) John B. Moore, Buffalo, N. Y., asks us several questions: 1. The current given by two 6-60 storage batteries when connected in series and in multiple? 2. A short method for figuring the wave length of loose couplers? 3. If a suitable form of acid rectifier would work in place of the crystal rectifier employed in wireless telegraphy for detecting the small currents in the receiving set?

A. 1. When two 6-60 storage batteries are connected in series the current obtained will have a voltage of 12 and the batteries will give 6 amperes for 10 hours, but when the storage batteries are connected in multiple the voltage will be 6 or equal to that of one battery, while the current output will be twice as great as from a single battery or 120 A. H.

A. 2. A rough method of calculating the wave length in meters of loose couplers is to multiply the length of the wire in feet on the primary only by 1.5.

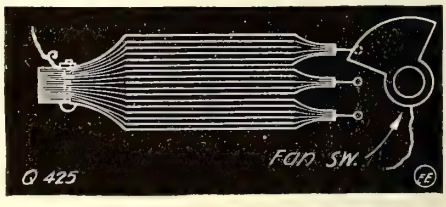
A. 3. The ordinary electrolytic detector is nothing more or less than an acid rectifier, for when the current flows in one direction it breaks down the film of hydrogen gas formed on the platinum point and when it starts to flow in the other direction the hydrogen gas is formed around the platinum point, which action is a check on the flow of the current.

INCREASING RECEIVING RANGE.

(424.) Russell Holcomb, Ottumwa, Iowa, writes us asking: 1. When an aerial is located between two hills what is the best method of increasing the receiving efficiency? 2. Are there any commercial or Government stations in Iowa?

A. 1. When an aerial is located between two hills the best method of increasing the receiving range would be to run a long single wire from one hill to the other with a lead-in from the center.

A. 2. There are no commercial or Government stations in Iowa, but several colleges have installed powerful radio transmitting apparatus, particularly the Iowa State College at Ames. This college makes a practise of sending the weather reports to the amateurs located in the State at noon. It is favorably placed for this purpose, being practically in the center of the State.



CONDENSER HOOK-UP.

(425.) Kilian Banfelder, Brooklyn, N. Y., desires to know: 1. If the connections for the condenser as shown in his letter are correct? 2. The wave length of a coil 3 inches in diameter and 14 inches long? 3. What high powered station he can receive with his apparatus?

A. 1. The connections shown may be used for controlling a fixed variable condenser, but, contrary to the general rule, the capacity will get smaller instead of larger as more condensers are thrown into circuit. We therefore suggest the use of the hook-up as shown in the accompanying illustration for controlling a number of small fixed condensers.

A. 2. The coil has a wave length of about 900 meters.

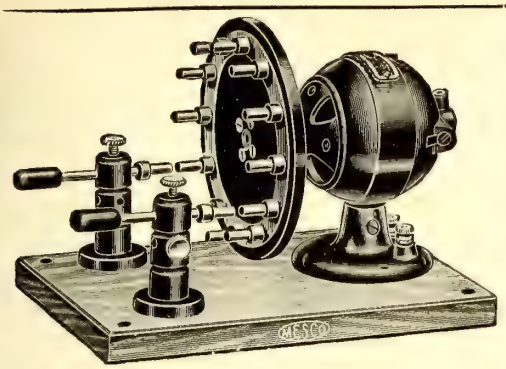
A. 3. With your apparatus you should have no trouble in receiving the high powered stations located around New York. You should hear Sayville, Arlington, the Brooklyn Navy Yard and commercial stations within a range of 200 miles.

Utilizing Fan Switch for Connecting Condenser Units.

AERIAL MASTS.

(426.) T. Weston Howard, Dexter, Me., desires to know if the iron masts used for constructing aerials should be insulated from the earth or grounded.

A. Some iron masts for aerial work are insulated from the earth or ground and others are not. The 800-foot mast at Tuckerton, N. J., is a part of the aerial and it rests on massive glass insulators at the base.



TESLA TRANSFORMER FOR WIRELESS SET.

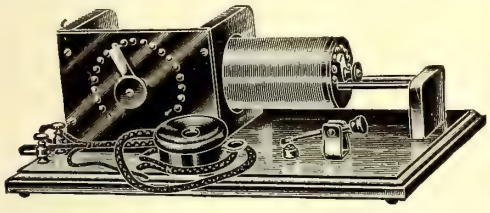
(427.) A. E. O'Brien, Jr., New York City, wishes to know: 1. Whether a Tesla transformer will improve the sending range of the wireless set. 2. How to receive undamped wave stations with an ordinary receiving set? 3. Why he cannot receive a station using a 1¼-inch spark

(*Continued on page* 578.)

"QUALITY" is our Wireless Watchword

SATISFACTION GUARANTEED OR MONEY REFUNDED OUR MOTTO

Mesco Rotary Spark Gap

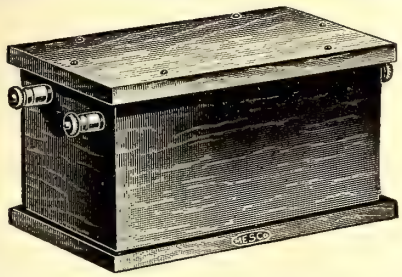


Emits a high musical note. Can be heard at greater distances than the note from the stationary type. Cannot be mistaken for static or other atmospheric disturbances. Produces pure wave of low damping decrement. Increases transmitting efficiency 20 to 30 per cent.

The rotating member has twelve sparking points mounted on a hard rubber disk and is carried on the motor shaft. Can be used on our spark coils or transformers up to 1 K. W. Has two stationary electrodes with special adjusting devices.

Our Globe Motor is used. Will operate on 110 A. C. or D. C. circuits; speed of 4,500 R.P.M. Also made with our Globe Battery Motor, which can be operated on a six-volt circuit.

List No.		Price.
222	**Mesco Rotary Spark Gap**, 6 volt	$12.00
223	**Mesco Rotary Spark Gap**, 110 v., A. C. or D. C.	13.00
216	**Rotary Unit Only**, with two Stationary Electrodes, 1 3/16 in. shaft	5.00

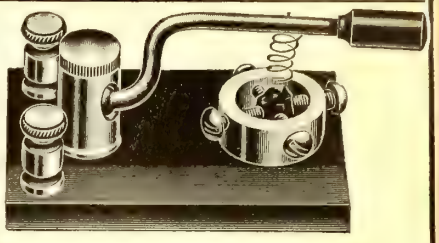


Manhattan Wireless Receiving Set

Consists of a loose coupler, fixed condenser detector, and an 80 ohm receiver with cord. Will tune up to 1,800 meter wave length on a 60-foot aerial. Can be tuned to waves over 4,000 meters with larger aerial and properly connected to loading inductance and variable condenser shunted across the secondary of the receiving transformer.

List No.		Price.
210	**Manhattan Wireless Receiving Set**	$10.00

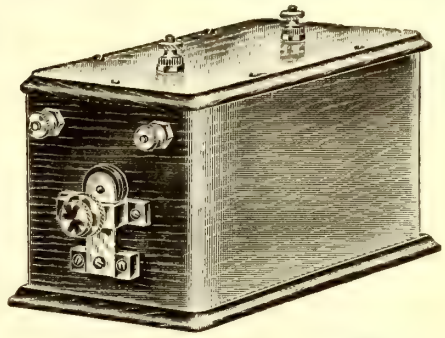
Mesco Intensifying Transformer



Used for intensifying signals received from any crystal detector by connecting an audion detector on the other side of the transformer winding. Used between two audion detectors, signals will be intensified 10 to 25 times.

As many as three of these transformers can be connected between audion detectors in cascade, forming an intensifier, making it possible to read signals not heard with any single known detector. Diagram of connections with full directions with each instrument.

List No.		Price.
224	**Intensifying Transformer**	$12.00



Mesco Universal Detector Stand

Has a heavy brass cup, with four binding screws; will hold crystals up to ¾ in. diameter. A hollow standard encloses a brass ball. Through an opening a brass arm with hard rubber handle is secured fast to the ball, making a ball and socket joint, allowing it to be adjusted at any angle or used in any position.

Hard rubber base 2¼x4¼x⅜ in. All metal parts nickel-plated. Remains permanently in adjustment under jars and vibrations of every description.

List No.		Price.
248	**Mesco Universal Detector Stand**	$3.00

Mesco Wireless Spark Coils

Have low current consumption. Best to operate on dry batteries. Contact points of heavy platinum iridium. Has primary condenser in case. Made for wireless work. Permits of close tuning. Spark at interrupter reduced to a minimum; spark is heavy; made in ¼-inch to 4-inch sizes. Our Manual gives all the technical points.

List No.		Price.
462	**Spark Coil**, 1 inch; can be operated on 6 Red Seal dry batteries	$5.40

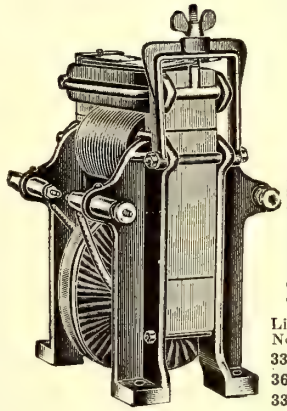
Mesco Codegraph



A dandy practice set for the beginner. Just the right kind for the apt boy.

The Codegraph Plate is of metal with insulated dots and dashes. The Pen is connected with the Red Seal Dry Battery and the Wireless Practice Set. When the pen is drawn across the dots and dashes it closes the circuit, and the buzzer sounds. It is possible to attach a sounder to the outfit and get the telegraph click also. A practical and efficient way of learning wireless and telegraph signals.

List No.		Price.
303	**Mesco Codegraph Set**	$2.50
304	**Codegraph Plate, Pen and Book**	1.00

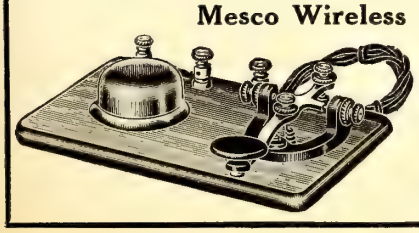
San Francisco Office, 604 Mission St.

Mesco Flexible WIRELESS TRANSFORMERS

Will make wireless apparatus 200 per cent. more efficient. When short circuited or when charging condensers does not consume any more power than the magnetic shunt is set for. Can be connected direct to alternating circuit.

List No.	Capacity.	Secondary Voltage.	Pr.
330	½ kw.	5,000 v.	$15
363	¾ kw.	10,000 v.	20
331	1 kw.	20,000 v.	25

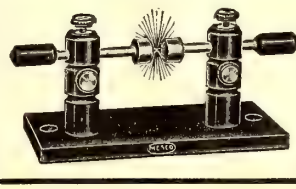
Mesco Wireless Receivers



Have powerful field magnets and thin diaphragms, and are very sensitive. Our No. 480 Double Head sets complete have been used in receiving commercial wireless messages over distances of 2,000 miles. All receivers are wound with silk covered copper wire.

Best steel obtainable used in construction of the permanent magnets. Users have had head sets for five years and over without any deterioration in sensitiveness. This cannot be said of any light-weight receivers.

List No.		Price.
480	**Double Head Band**, with six-foot green silk cord and two receivers, 1000 ohms each	$6.00



Mesco Wireless Practice Set

Comprises a regular telegraph key, without circuit breaker, a special high pitch buzzer, one cell Red Seal dry battery, and four feet of green silk-covered flexible cord. The main object of the set is to enable the beginner to master the wireless code, and the buzzer reproduces the sound of the signals of the most modern wireless stations perfectly.

List No.		Price.
342	**Wireless Practice Set**, with battery and cord	$1.50

Mesco High Efficiency Spark Gap

Adapted for stations up to ¼ K.W. capacity. Base is of polished hard rubber. Standards are of hard rubber composition of the highest insulating properties. Hard rubber ends on the brass rods permit the length of the gap to be varied, while sending. Spark terminals are of zinc, and are renewable.

List No.		Price.
465	**High Efficiency Spark Gap**	$3.00

QUESTION BOX.

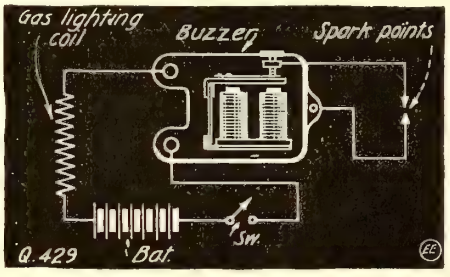
(*Continued from page 576.*)

coil located 6 miles away when he can get Arlington during the day?

A. 1. The Tesla transformer of the regular type will be of practically no use in a wireless station and an oscillation transformer is not advised except with powers of ¼ K. W. or more.

A. 2. You may receive undamped wave stations with an ordinary wireless set by connecting the tikker in series with the secondary circuit. The tikker can be built according to instructions that have appeared from time to time in this journal.

A. 3. The 1½-inch spark coil set which will not send signals 6 miles is, no doubt, poorly tuned for the best results. It is necessary to tune the set carefully and to get the closed and open oscillating circuits in resonance before the maximum range can be covered.



DYNAMO PLANT.

(428.) Oscar Stulman, Baltimore, Md., wishes to know if it is practical to drive a 24-watt dynamo with an ordinary sewing machine by connecting the pulley and treadle of same with the dynamo by means of a belt?

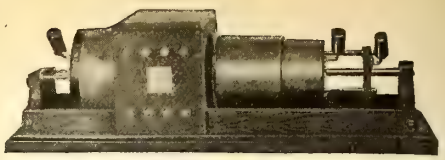
A. The small dynamo can be attached to a plain sewing machine by the regular belt and you can drive it up to full power by means of the treadle. It will light from 8 to 10 6-volt Tungsten lights, depending on the candlepower of same, which should not be over 1 candlepower each. With this arrangement you can also charge storage batteries, although the process is very slow.

JUMP SPARK FROM BUZZER.

(429.) Sigmund Senz, Bronx, N. Y., wishes to know: 1. How to obtain a jump

Jump Spark Produced from Buzzer.

spark from a buzzer? 2. If an ordinary alternating current magneto may be used for ringing an electric doorbell?



A. 1. You can obtain a minute jump spark from a buzzer by using the connections shown herewith. For best results it is necessary to use quite a number of batteries on the buzzer and to have a rather long throw on the armature. The spark will not be more than 1-16 inch at the most, and this method is a very poor manner for obtaining a jump spark.

A. 2. You may ring a polarized bell with an alternating current magneto very easily, but we doubt if this machine will deliver enough current to ring an ordinary electro-magnetic bell.

GAS FOR BALLOONS.

(430.) Claude Martin, Brownwood, Tex., wishes to know what chemicals will generate a powerful lifting gas that would be safe and non-explosive and the type of generator required.

A. The gases used for inflating balloons is hydrogen gas or illuminating gas. The former is obtained by dissolving scrap zinc in a 4 to 1 solution of sulphuric acid, and the latter is purchased from a local gas plant. We know of no gas with any power-

ful lifting properties that is not explosive and they are all more or less dangerous.

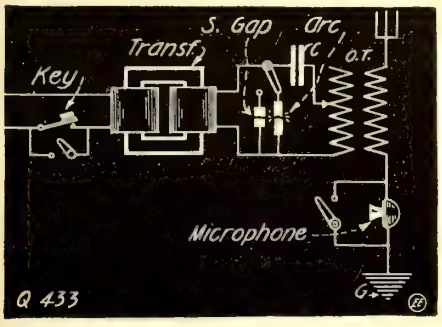
60 CYCLE TRANSFORMER ON 25 CYCLE CURRENT.

(431.) Clayton B. Shelley, Barker, N. Y., wishes to know: 1. If it is possible to operate a 60-cycle transformer on a 25-cycle circuit? 2. Why it is that when N. A. A. is sending on low wave lengths the signals die out, but when he moves the secondary of the coupler in and then draws it out to its original position the signals become strong again?

A. 1. A 60-cycle transformer may be operated on a 25-cycle circuit by using a resistance or a choke coil in series with it. The output of the apparatus will not be up to the full rating of the transformer.

A. 2. It appears to us that the rods on which the secondary slides are corroded and the spring makes poor contact with them. When the secondary is slid along the rod it has the effect of scraping the rod clean and the contact is much improved. This may account for the signals coming in strong again.

SAL-AMMONIAC CELLS.



(432.) D. W. Fleming, Ottawa, Kan., asks: 1. If the carbon in the sal-ammoniac cells requires renewing from time to time? 2. If such cells may be used for lighting small lamps?

A. 1. The carbon in the sal-ammoniac cells does not need renewing, but it may occasionally be necessary to put the carbon in boiling water to drive out the salts that settle in the pores.

A. 2. These batteries may be used for lighting small lamps for 2 or 3 minutes at a time, but their amperage soon drops off, due to the polarizing of the carbon.

WIRELESS TELEPHONE SET.

(433.) J. B. Starkweather, Newtonville, Mass., desires to use a ¼-K. W. Clapp Eastham transformer in a wireless set and

Using A. C. Radio Transformer for Telegraphic or Telephonic Transmission.

in a combination wireless telephone and telegraph set, the supply current being alternating current.

A. We append a diagram of connections which will enable you to use the apparatus as either a wireless telephone or telegraph. As will be seen, a spark gap and arc may be thrown across the secondary terminals of the transformer as desired. The arc used may be of the regular carbon type or one utilizing carbon and copper rods and built according to the usual practice in wireless telephony. Although the 60-cycle alternating current supply will cause more or less of a hiss the outfit will work satisfactorily for distances of 5 miles. It is preferable to use an oscillation transformer, and the microphone transmitter is connected in the ground lead, while the key, which may be short-circuited by a switch when the outfit to be used as a wireless telephone, normally operates the set.

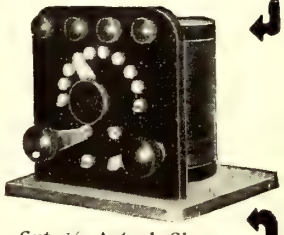
NEW WIRELESS WONDER

THE INSTANT RADIOGRAPH

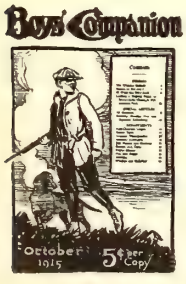


Greatest invention of the Age. The result of years of experimentation.

Abolishes detector troubles and adjustments—
No more delays—no more lost time and messages
Pick up your receivers any time, Summer or Winter, in any atmospheric conditions and—

You Can Receive Instantly Without Any Adjusting

3,000 miles is latest record of the Instant Radiograph.
It is wonderful, but true, you cannot get the Instant Radiograph out of adjustment no matter how you knock it about. Try it yourself, hit it with a hammer while in use.
Vibrations, jars, knocks cannot affect it as there are no fine adjustments to make—no batteries—nothing to wear out—no operating expense whatever.



INTRODUCTORY PRICE FOR FEBRUARY **$3.00**

Cut ¼ Actual Size.

The Instant Radiograph is more efficient than any detector on the market, as there is nothing to adjust.
The Instant Radiograph is beautifully and solidly constructed on a heavy base of hard rubber 4 x 4 inches square with rounded corners and high; binding posts are made of non-corroding metal, heavily silver plated, and have heavy rubber-covered thumb screws, preventing current leakage. **All contacts are large, non-corroding, heavily silver plated, of large size and will last a lifetime. This is a wonderful instrument of distinctive appearance that you will be pro ud to have in your wireless station.**
The Radiograph is the greatest recent invention in the Wireless field. Its value is priceless and as we want every professional and amateur operator on land and on board ships to use it, we have decided to make an introductory price of $3.00 for a limited time only. This is only one-third of the price at which it should be sold. Send your order at once. **Send for free Catalog E of the Instant Radiograph.**
Free—Instant Radiograph—a book you need. "Radio Stations of the World." A complete authentic list of call signals of every public wireless station. Price, only 50c.

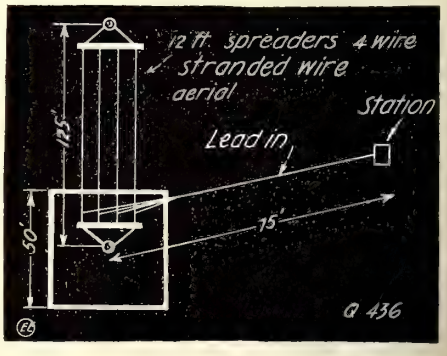
BOYS' COMPANION, 1122 The Temple, CHICAGO, ILL.

BICYCLE HEADLIGHT.

(434.) W. L. Rodrigues, Charleston, S. C., asks for data on the method of attaching a dynamo to his bicycle to enable him to light a small headlight for same.

A. A dynamo that would be suitable for use on a bicycle would be a 24-watt machine. This should be bolted to the bicycle frame under the seat and a friction pulley on the shaft should make contact with the rear wheel. This machine delivers 6 volts at full speed. And when traveling 5 or 6 miles an hour this voltage will be delivered. Four small dry cells should be connected across the wires to keep the light lit when traveling below this speed. A tungsten lamp should be used so that it would not be burned out when the voltage rises above normal. You can use a clamp for connecting this to the frame and no trouble should be encountered.



K. V. A.

(435.) Noble A. Allen, Beacon Falls, Conn., writes us asking for the explanation of the term "K. V. A." when applied to high tension alternating currents. As an example he wishes us to figure the horsepower of a transformer stepping 11,000 volts down to 440 volts, which is rated at 100 K. V. A.

A. The expression K. V. A. extended means kilo-volt-ampere. Since the volts times the amperes equal the watts, the expression really means kilo-watts. However, in alternating current work it has been found that the actual voltage and amperage in the circuit and registered on the ammeter and voltmeter and that registered by the wattmeter do not correspond. This difference is known as the "power factor." When the power factor is one or unity, the kilo-volt-amperes refers to kilowatts. However, when the power factor is other than one the expression "K. V. A." is used to indicate that the volts and amperes as actually flowing in the circuit are meant and the wattmeter reading is to be disregarded. Therefore 100 K. V. A. with a power factor of 1 or unity is equal to 138 horsepower. This figure is obtained by dividing the 100 K. V. A., or kilo-watts, by .746 K. W., which is the equivalent of 1 horsepower.

EFFICIENT AERIAL.

(436.) L. L. Baker, Tulare, Cal., sends us a problem on aerial construction. He has

Special Antenna Layout.

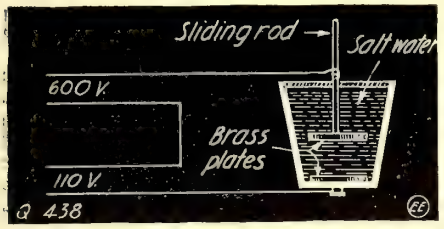
a mast 95 feet high in the center of an area 50 feet square. The station is to be located 75 feet east of the mast, and he has means of fastening an aerial 60 feet high 125 feet north of the plot of ground. He desires to know which would be the most efficient aerial under these conditions.

A. We show herewith the plan of an aerial that will be most efficient under the

conditions mentioned in the question, and it will have a natural wave length of approximately 350 meters.

BUZZER TRANSMITTING.

(437.) Charles Welsh, Philadelphia, Pa., sends us a drawing of a buzzer set and wishes to know: 1. If it is practical? 2. How to connect a tuning coil and loose coupler? 3. What could be added to increase the sending radius of a buzzer set.



A. 1. The hook-up you show of the buzzer transmitting outfit is impractical for several reasons. The principal reason is that the buzzer A will not operate, due to the fact that the vibrator on this buzzer is not connected in the return circuit to the battery.

A. 2. A tuning coil is generally used as a loading coil in connection with a loose coupler. This is accomplished by connecting the instrument in series with the aerial lead.

A. 3. To increase the sending radius of a buzzer outfit the addition of a kick coil in the circuit will have the effect of increasing the range. This coil will cause larger sparks at vibrator points, which will in turn energize the aerial in a more powerful manner.

CURRENT REDUCER.

(438.) Geo. Outen, Oberlin, O., asks: 1. How to reduce 600 volts direct current to

Use of Water Rheostat in Reducing Voltage.

110 volts? 2. The wiring diagram of a receiving set using two audions. 3. Is it necessary to use an interrupter on a 1-K. W. open core transformer operated from 110 volts direct current?

A. 1. The cheapest method of reducing 600 volts direct current to 110 volts is by the use of a water rheostat or some form of wire resistance. The rheostat may be made according to illustration herewith, or if a wire resistance is preferred you may use 2 pounds of No. 20 German silver wire wound on some sort of a form. Either of these arrangements will pass 5 amperes.

A. 2. For hook-up on a set using two audions we refer you to page 489 of the January, 1915, issue of this magazine.

A. 3. The usual practice when a 1-K. W. transformer is to be operated on a 110-volt direct current supply is to utilize a rotary converter. The rotary consists of a machine that takes direct current on one side and delivers alternating current on the other. This is the best method of operating a transformer, as an interrupter for handling 10 amperes at 110 volts would be very noisy and expensive.

ELECTROLYTIC INTERRUPTER.

(439.) Milford M. Henderson, Salt Lake City, Utah, desires to know: 1. The constituents of the electrolyte in an electrolytic interrupter. 2. What range can be covered with an aerial 35 feet long and 25 feet high, using a buzzer and condenser and standard hook-up for such an arrangement. 3. A wiring diagram for three ½-inch spark coils and one make and break coil with an electrolytic interrupter.

A. 1. The solution used in electrolytic

Everyone is talking about the Electroset Co's

ARLINGTON TESTED MINERALS

A.T. GALENA A.T. SILICON

Why Buy Minerals on a Gamble?

The least expensive and the *most important* part of your wireless equipment is the mineral in your detector.

An expensive receiving equipment will do only mediocre work if the detector is not sensitive.

Don't Neglect This Important Point.

It costs mighty little to get extremely sensitive minerals. But it requires caution. Look carefully where you buy. To be *sure* accept only

Electro-Set Wireless Minerals.

Every package marked thus

GENUINE ELECTRO-SET MINERAL

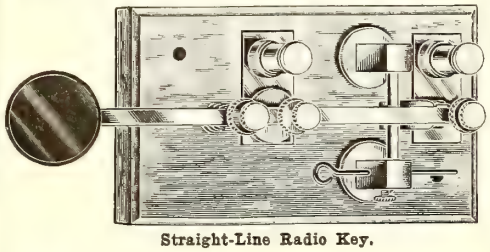
2 NEW BUNNELL WIRELESS SPECIALTIES

The Jove Crystal-Detector-Holder is the simplest, handiest and most perfect arrangement yet produced. It holds crystals without using clamp screws.

It firmly holds crystals of different minerals at the same time—change of contact from one to the other can be instantly made; a sensitive point quickly found, and the correct pressure held constantly, all without using a single screw or nut. It is designed and finished in our well-known high grade style. Mounted on dark enameled porcelain base with metal parts nickel-plated and highly polished. Postage weight, 1 lb.
Price, Net $1.00



Jove Crystal-Detector-Holder.

The Straight-Line Renewable-Contact Radio Key is much superior to other types of Radio Keys.

Not only are the contacts renewable; but, no matter how much worn, full contact surface can be maintained between them, and the lever retains its normal horizontal position.

This is accomplished by mounting the upper contact on an adjusting screw, which is threaded through the lever and held in position by a check nut. The lower contact is so arranged that it may be loosened for adjusting.

By holding the lever down, with lower contact loose, and then clamping it, perfect surface alignment between the faces of contact pieces is secured, and thus fading or irregularity in strength of signals caused by varying resistance of contact points is eliminated and the contact pieces may be practically used up before renewal becomes necessary.

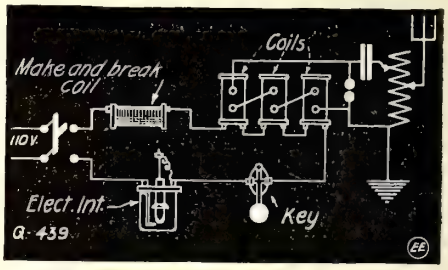
Straight-Line Radio Key.

Another desirable feature of our Straight-Line Radio Keys is the self-clamping binding posts with which they are equipped. These posts make loose connections impossible.

The Keys are mounted on heavy, polished marble bases (6 in. x 3½ in. x 1 in.). The metal parts are heavily nickel-plated and polished, making a strikingly handsome symmetrical instrument.
Price, with ⅜ in. hard silver contacts; postage weight, 4 lbs..... net, $7.50

Send for descriptive circular and copy of our Wireless Catalog.

THE J. H. BUNNELL CO., Inc., Electrical Manufacturers, "Dept. EX", 32 Park Place, New York City



Jensen Electric Co.
RADIO APPARATUS and SUPPLIES
SEND FOR LITERATURE
1949 Huron Street CHICAGO, ILL.
We are a distributing point for AudioTron Bulbs $6.50

IF THE ELECTRICAL EXPERIMENTER is good reading once in a while, it is better when read regularly. To make sure that you get your copy, you should subscribe. There's a convenient coupon and a wonderful offer on page 597

interrupters consists of a mixture of 1 part sulphuric acid and 5 parts water, or a 16⅔ per cent. solution.

A. 2. With an aerial of the size mentioned and the buzzer transmitting outfit you may cover 1 mile under very favorable conditions. The hook-up suitable such an outfit was given on page 352 of the November, 1915, issue of this magazine.

A. 3. We give herewith a diagram of connections for wiring three ½-inch spark coils. The make and break coil should be connected in circuit as shown to control the input to the interrupter. We do not

Operating Three Spark Coils with Electrolytic Interrupter.

advise the use of such small coils with an electrolytic interrupter, as the unduly high voltage of the secondary has a tendency to puncture them when used for a short time.

POULSEN TIKKER.

(440.) LeRoy D. Brown, Winkelman, Ariz., wishes to know: 1. What instruments are required to receive messages from a station using a Poulsen Arc? 2. How to protect his instruments from being destroyed by a near-by high power radio station? 3. The construction of a ¼-K. W. transformer?

A. 1. To receive messages from a Poulsen station you will require some form of a tikker or oscillating audion. The former consists of a special form of circuit breaker and can easily be made by mounting a small brass disc on the shaft of a toy motor and then filing a groove around the edge of the disc with a triangular file. A fine spring brass wire is laid in this groove and connections are made to the motor frame and the fine wire. The apparatus is connected in series with the 'phones and has the effect of breaking up the high frequency oscillations so that they become audible in the head set.

A. 2. To protect the instruments from near-by high power stations the usual practice is to connect a micrometer gap across the primary leads of the loose coupler. A Geissler tube may be used for the same purpose, the extra strong signals being conducted direct to the ground.

A. 3. A ¼-K. W. transformer may be constructed on a square iron core having a cross section 8 inches square and outside dimensions of 6¾x5⅜ inches. The secondary core is insulated with a layer of mica and two layers of Empire paper. The secondary consists of 2 pounds of No. 34 enameled copper wire, or 16,000 turns. The primary is constructed from 3½ pounds of No. 16 D. C. C. wire, which will be enough for 485 turns. The input on this transformer will be 3½ amperes at 110 volts.

FILMS FOR CONDENSER.

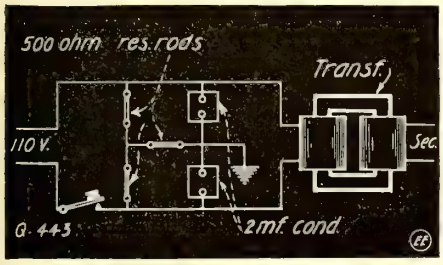
(441.) Theo. C. Braun, Jersey City, N. J., wishes to know if film negatives can be used as the dielectric in a condenser for receiving purposes.

A. The material used in making films is ideal for constructing small receiving condensers, but it is necessary to remove the emulsion from same. The sensitive mix-

ture used on films contains silver nitrate, which is a conductor, and it would have to be removed by soaking in water and carefully scraping the film.

TRACTIVE MAGNETS VS. SOLENOIDS.

(442.) James Dowdall, Brooklyn, N. Y., desires information on: 1. Which is the best type of magnet to draw up a weight of 1 pound a distance of 2½ inches from the pole pieces? 2. Where to purchase platinum wire as used in gas stove igniters and its price? 3. Whether dry cells will perform their work if exposed to freezing temperature?



A. 1. When a weight is to be moved 2½ inches it is the usual practice to utilize a solenoid for this purpose. A solenoid having a magnetic pull of 2½ inches requires much less current and is much smaller than any magnet that will do this work.

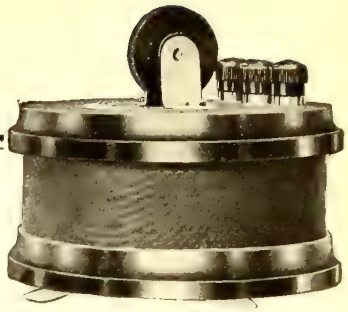
A. 2. The platinum wire used in gas stove igniters is of very small size, and we do not know if same can be purchased separately. However, you may take up the matter with dealers in experimental apparatus who may be able to quote you on this fine wire. Refer to our advertising columns.

A. 3. A dry cell will perform its work perfectly when subjected to the temperature of freezing water, but when the cells are cooled to such a point where the small amount of moisture in them is solidified the resistance will be increased and the output lessened.

KICK-BACK PREVENTER.

(443.) Raymond Guy, Tottenville, N. Y., asks us for information on: 1. The construction of a kick-back preventer. 2. The wave length of an aerial 55 feet long and 40 feet high. 3. The receiving transformer sold by the Colby Telegraph School, Auburn, N. Y.

Hook-up of Radio Transmitter with Protective Condensers and Resistance Rods.



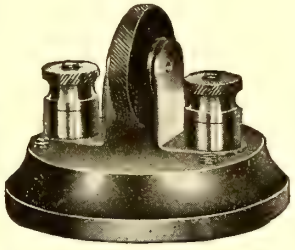
A. 1. A kick-back preventer can be made from 2 one micro-farad telephone condensers which are connected in series across the primary of the transformer and the center connection grounded, as shown in the accompanying illustration. Three resistance rods of 500 ohms' resistance may also be used for the same purpose, as shown.

A. 2. The wave length of the aerial is approximately 165 meters.

A. 3. The receiving transformer sold by the Colby Telegraph School consists of two secondary coils with a slider on each. Inside these coils the primary slides back and forth. By adjusting the position of the primary and the inductance of the respective secondary coils good selectivity is obtained and the signals come in loud.

AUDION QUERIES.

(444.) N. G. Moser, Topeka, Kan., desires: 1. Explanation of the construction of an oscillation gas valve. 2. The theory of the action of such a valve when used as an amplifier and as an oscillation generator.

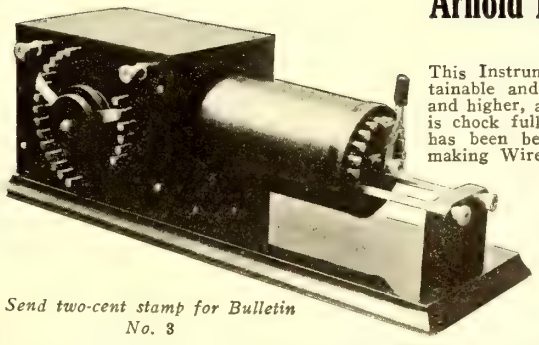


CRYSTALOI

A Highly Sensitive and Permanent Wireless Detector That Has Made A Great Record

TYPE AA. SUPER-SENSITIVE
DIMENSIONS 4" x 3½".
PRICE, $6.00
Mailing Weight, Two Pounds

The **CRYSTALOI DETECTOR** will do for you exactly what you would have a detector do. It will put you in touch with the *Distant Stations*. It is not affected by near By-Stations. It is capable of the finest adjustment and will last a life time if properly cared for. We guarantee every instrument to be and do everything we claim for it. Ask any one of the thousands that are using them—they are all for us.



CRYSTALOI—Type 0—$3.50
Postage, 10 cents

OUR NEW MINIATURE WIRELESS CATALOG describing our complete line of Receiving Apparatus can be had for five cents in stamps.

REMEMBER WE ARE SPECIALISTS in wireless Receiving Apparatus and our products are of the highest grade obtainable.

Eugene T. Turney Company, Inc., 2595 Third Avenue NEW YORK CITY

Arnold Navy Type Loose Coupler

PRICE, $15.00

This Instrument is made of the best Material obtainable and is equal to others selling for $18.00 and higher, all fancy prices and frills are eliminated, is chock full of value and is made by a man who has been before the public for the past 5 years making Wireless apparatus.

It will tune up to 3,500 meters.

I also stock the finest line of switch points, Hard Rubber knobs, Cabinets and accessories on the market. Prompt delivery of all orders has distinguished me.

"MONOTONE" QUENCHED SPARK GAP

Why dissipate your radio energy in sound and light waves? Carry it to the diaphragm of the distant receiver on pure waves of **Radio Energy.** Every station should be equipped with "Monotone" Quenched Spark Gaps for penetrating great distances. Span that "freak" distance every night. Silent in operation. Arcless. In single units as illustrated for spark coils. Two units in series and multiple for every quarter K. W. power of transformer. Price per unit, $1.50, prepaid.

RICHARDSON COMPANY, Commerce Bldg. ERIE, PA.

LOOK! A NEW CHAMBERS COUPLER No. 744, PRICE ONLY $4.50

Positively unequaled for the money. Is 6" high, 6" wide, and 14" over all. Wound with Enameled wire, and has a very unique slider. Woodwork mahogany finished. Try one, you will not be disappointed.

5c. in stamps brings our 64-page illustrated catalogue, B-B-24. None otherwise.

M. MUELLER, 18 Devonshire Street, BOSTON, MASS.

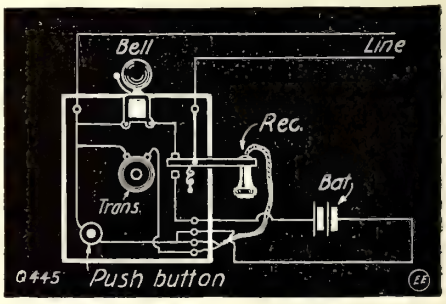
READ the Classified Advertisements in this issue. They are small but contain big bargains and opportunities.

3. The method by which the recent tests from Arlington were carried out.

A. 1. The oscillation gas valve or audion consists of a glass bulb within which is mounted a small lamp filament, preferably of tungsten or tantalum, a small grid made by winding nickel wire in a zigzag shape and a small plate of nickel. The bulb is exhausted by means of a vacuum pump and sealed off. Connections are made to the ends and the center of the filament, to the grid and to the plate or wing.

A. 2. Such a valve and its operation as amplifier is discussed at length in the January, 1915, issue of this magazine on page 488, but, briefly speaking, the theory is as follows: When energy flows into the tuning apparatus it causes an increase in the number of ions given off by the glowing filament. These ions lower the resistance between the grid and wing, and cause a momentary flow of current in the phone circuit. This circuit contains inductance and capacity, and will therefore oscillate. This current oscillating in the phone circuit reacts on that in the tuner circuit, which in turn further affects the ions flowing through the vacuum, causing an increase of the oscillations in the wing circuit. This action repeats itself and explains the amplification of signals. The above effect takes place when the grid circuit is not tuned to the same wave length as the tuner circuit. When the inductance and capacity in the wing circuit is nearly equal to that in the tuner circuit the oscillations set up will react on the incoming signals to produce beats. By this means it is possible to receive undamped waves.

A. 3. In the recent radiotelephone tests from Arlington to Honolulu and Paris 300 Kenotron tubes were used at the transmitting end and each tube handled ½ kilowatt of energy. The microphones were connected in the circuit in such a manner as to control the ionic flow in these tubes. In this manner the high frequency currents flowing to the aerial were controlled. At Honolulu and Paris elaborate receiving sets were installed which included audion amplifiers.



MAGNETO CONSTRUCTION.

(445.) Arthur Paul, Hilton, N. J., sends us a drawing of the armature of a small magneto he is constructing from parts of a motor-cycle magneto and desires information: 1. On the size of the wire, etc., required to finish the machine. 2. Why the coupler he has constructed will not respond to wireless signals, although it seems to be all right when tested with battery and buzzer. 3. The connections for a small, short-range telephone he has under construction.

A. 1. The armature of your magneto should be wound full of No. 24 S. C. C. or enameled wire and a two-part commutator placed on the shaft. The leads from the coil are to be soldered to the segments of the commutator in the usual manner, and two brushes should be arranged to take off the current. With this arrangement and the machine running at about 1,800 r.p.m., you will obtain in the neighborhood of 8 volts and 4 amperes if the magnets you use are of standard strength.

A. 2. It appears that there is an open circuit in your coupler through which the buzzer test has no trouble in flowing, but the current received in the aerial is not strong enough to break down the resistance at this point. We suggest that you examine the coupler carefully and look for open circuits, paying particular attention to the connections between the secondary coil and the leads to the rest of the instruments.

A. 3. We show herewith the proper diagram of wiring for your short-range tele-

Short Range Telephone Set Hook-up.

phone. The transmitters and receivers are connected in series, and the batteries at both stations should assist each other.

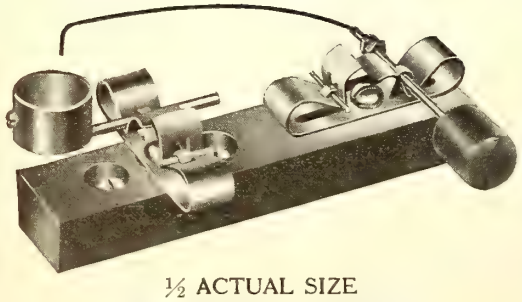
AUDIONS.

(446.) D. Currair, Binghamton, N. Y., asks us for information on the construction of the audion detector.

A. In our answer to questions No. 444 we give information on the constructional details of audion detectors. We would like to say that it is practically impossible for an amateur, unless equipped for extra fine glass blowing, to construct these instruments, and only satisfaction can be obtained from the factory-made apparatus.

TRANSFORMERS.

(447.) Carl L. Flory, Eaton, O., writes us, stating that he has a transformer which steps 110 volts up to 880 volts. He desires to know the dimensions of a transformer which would step this 880 volts up to 20,000 volts or more for wireless purposes.



A. We do not approve of the use of two transformers as you suggest, although the scheme will work. It is much cheaper in the end, and the apparatus will be more efficient, if a single transformer is constructed that will deliver 20,000 volts when operated direct from the 110-volt supply.

XMAS CHEER VIA WIRELESS.

Christmas greetings by wireless were sent by President Oswald Becker, of the Davenport (Ia.) Rotary Club, to the heads of Rotary clubs in eleven cities in Iowa and to Omaha, Neb.

The novel form of "Merry Christmas" was relayed out of Davenport by W. H. Kirwan, construction superintendent of the Otis Elevator Co., who has established one of the most powerful radio stations in the Middle West at his home.

Since setting up his radio station Mr. Kirwan has organized a large number of the young men interested in the science into a club for study and practise. He was formerly in the naval service of the United States and served as an electrician in the Spanish-American War. He daily intercepts messages from the United States Government station and from stations all over the United States.

PATENT ADVICE

Edited by H. GERNSBACK

In this Department we will publish such matter as is of interest to inventors and particularly to those who are in doubt as to certain Patent Phases. Questions addressed to "Patent Advice" cannot be answered by mail. Sketches and descriptions must be clear and explicit. Only one side of sheet should be written on.

MERCURY ARC LAMP.

(43.) R. E. Benson, Trinity, Texas, has submitted to us a novel mercury arc to be used in connection with a motion picture machine. He wishes to know if his invention is practical and whether it will do the work. He furthermore desires to know if it would be a paying improvement. Also, from whom he can obtain explicit information concerning the mercury arc.

A. The scheme submitted is indeed novel and although it will not work exactly as shown in our correspondent's drawing, for the reason that the mercury arc cannot be maintained in a fixed position but must be changed when lighting and extinguishing, we think that by adding several minor improvements the idea can be worked out successfully. We think that an improvement of this kind might work out to advantage, although we do not venture to say that the public would like green moving pictures which result from using a mercury arc. However, by interposing color filters, the greenish light might be done away with, although this is a very difficult thing to do with the mercury arc lamp for the reason that it has no red rays in it whatsoever.

We would advise our correspondent to get in touch with the Cooper Hewitt Co., Hoboken, N. J., and by sending for their catalogs, etc., much information can be had as to the mercury arc and its functions.

NON-REFILLABLE BOTTLE.

(44.) M. Robertson, Nyack, N. Y., submits sketch and description of a non-refillable bottle; he desires to know if it is patentable and if it is of any value.

A. This bottle, like many other non-refillable bottles of which several thousand have been patented in the past, undoubtedly shows some novel points, but we are not sure whether it can be patented on account of so many patents existing in the art. The wisest thing to do would be to get in touch with a patent attorney and obtain references on non-refillable bottles and see what has been accomplished before. There is undoubtedly a market for a simple non-refillable bottle that should have the following advantages:

The device must be cheap to construct and must be made in such a manner that it cannot be detached from the bottle without actually breaking the latter. It should not have any metal parts if possible, as some liquids, particularly spirits, do not improve if they come in touch with certain metals.

AUTOMATIC ELECTRIC CONTROLLED GATES FOR GRADE CROSSINGS.

(45.) Bertram Farnham, East Saugus, Mass., claims to have invented a system of automatic electric controlled gates for grade crossings. The train is supposed to ring a bell, work a signal and put down the gates and raise them again after passing of the train. He wants to know if such a device should be patented and if it is of any value.

A. As stated before in these columns, the railroads as a rule do not favor electrically controlled systems as they are not reliable enough from one season of the year to the other, but without knowing the merits of the invention it is impossible to state our full opinion.

In some sections of England there exists to-day automatic electric controlled gates, but we do not know how successful they have been. There is, however, no doubt in our mind that systems of this kind will come into vogue more and more.

ANTI-COLLISION DEVICE FOR RAILROADS.

(46.) V. G. Johnston, Marshallville, Ga., informs us that he has a satisfactorily working device for the prevention of head or tail-end collisions on railroads by employing a method for signaling in the cabs of the respective locomotives in danger. Our correspondent states that the whole outfit will cost approximately $10 to install, and he furthermore wishes to know our views concerning the device, if the railroads would be interested in such an idea provided the scheme works entirely satisfactorily.

A. Without knowing the nature of the invention, it is impossible to give intelligent advice. Merely a low price would not interest the railroads if there were some functions connected with the device that did not make it entirely "fool-proof" under all conditions.

Railroads usually look askance at devices of this kind, particularly electric devices that work by contact, for the reason that they work well in good weather, but they might not work in case of a snowstorm, when ice covers the right of way or in case of a wash-out.

It is always well to bear in mind that the average railroad accident does not happen under usual conditions, but rather the unusual, where the human element does not perform its functions as it should. The average railroad man, although he is cautioned against it, thinks that certain accidents will never happen on account of certain conditions, and it is usually on account of taking things for granted that accidents do happen.

We would advise our correspondent to get in touch with a patent attorney as soon as his invention has been perfected.

PATENTS

IF YOU HAVE AN INVENTION which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention, and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of seventy years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand-Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to **Patents, Trade Marks, Foreign Patents,** etc.

All patents secured through us are described without cost to the patentee in the *Scientific American.*

HOW VESSELS AT SEA SIGNAL THROUGH THE WATER.

(*Continued from page 534.*)

tween two discs drawn together on the tube by a one-inch steel rod and a right-and-left-handed screw thread.

Telegraphing with this Fessenden oscillator is accomplished by means of an ordinary telegraph key placed in the main armature circuit. No undue sparking takes place at the contacts of same; this is due to the fact that the armature has substantially no self-inductance and thus no eddy currents are generated in the apparatus. A 500-cycle alternating current is used. The apparatus is usually of considerable size and is rated at several kilowatts.

When the oscillator is placed on a vessel or hung overboard, a large water-tight diaphragm is attached to it. This particular form of oscillator was first tested between a lightship and a tug 31 miles apart. A later test under severe conditions has established the fact that signals may be transmitted reliably upward of 20 miles, while the vessel transmitting the signals is running at full speed. Quite remarkable indeed is the fact that the Fessenden oscillator may be in turn used for receiving the sound waves, due to the fact that the alternating current reaction is similar to that of motors of the alternating current induction type. In most cases, however, the usual microphone picks up the sound waves which are transmitted by such oscillators.

A very important field for these submarine signals is that involving submarines. These little terrors of the undersea, especially when running submerged, have scant means at their command to communicate with any sister vessel or with the mother ship. In the United States navy tests made

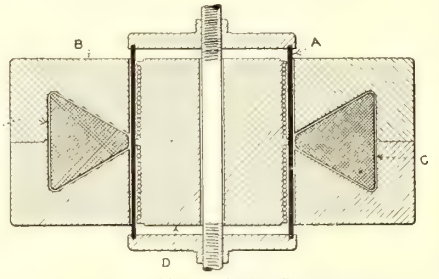

Fig. 3. Sectional View of the Fessenden Oscillator for Submarine Telegraphy.

with these submarine signals some time ago reliable communication was established and maintained for a distance of several miles between boats. It is also possible for a submarine to signal any vessel equipped with submarine signaling apparatus that she is in distress, and it is also possible for lifeboats to carry a submarine signal bell, so that in case they should be estranged or lost during rescue work at sea they could send out distress signals giving their locations, etc., in order that the ship to which they belong will know what to do. Science will eventually rob the sea of all its terrors, or at least those besetting the traveler.

THE RADIO PROFESSION.

One profession that is not overcrowded in the United States is that of the radio operator. The United States in case of war would find it a difficult matter to secure enough professional operators for all of the ships and stations. In that emergency the Government's only resource would be the 250,000 amateur operators in all parts of the country, who really accomplish excellent work in this interesting field. Many are just bungling beginners, of course, but there are also a large number of competent operators among them.

It Holds the Bit

Here's an extension bit holder with chuck so small it will follow into a 5/8-inch hole.
Yet in this
MILLERS FALLS
EXTENSION BIT HOLDER No. 6
the jaws are of strongest steel made in one piece and they *hold the bit* firmly and securely. Outer sleeve telescopes over inner spindle combining lightness and strength. Takes up little room in the kit—extended easily, in a second.
Collapsed 16½ inches, extended 24 inches.

Build a WAR AEROPLANE

"Ideal" accurate Scale Drawings enable you to build EASILY exact 3-ft. **Flying** Models **of those Aeroplanes now** used in the European **War.** Study Aeronautics. Build a model man-carrying machine. We will send you 3-ft. Scale Drawings with **building** and **flying** instructions at following prices:

Curtiss Flying Boat	25c
" **Military Tractor**	25c
" Hydroaeroplane	35c
Nieuport Monoplane	25c
Bleriot Monoplane	15c
Taube Monoplane	25c
Wright Biplane	25c
Cecil Peoli Racer	25c

Complete Set of Eight, $1.60 Postpaid

Get our 50-page Aeroplane Book, with full information about Model Aeroplanes, parts, prices, etc. 5c. postpaid.

IDEAL AEROPLANE & SUPPLY CO., 76-82 W. B'WAY, N.Y.

THE TRENCH TRACTOR.

(*Continued from page* 536.)

induce the men to leave their trench, and, secondly, if they persist in remaining they stand a good chance of being bayoneted or otherwise becoming exterminated by their foes. Incidentally the tractor, being enveloped in a cloud of steam, is protected in a certain degree from the enemy's shell fire.

If a dozen or more tractors of this kind were sent against a line of trenches, it is difficult to see how the enemy could hold them.

"So far so good," my wise friends will observe; "but suppose the enemy, too, has Trench Tractors. Suppose that the 12 French Tractors rush against the 12 German ones. What then?"

In answer to this the writer points to the submarine war and its recent collapse. As long as the submarine could not be combated it raised havoc, the same as the Trench Tractor will raise havoc till it can be combated. But the submarine is now combated by the electric submarine "ear," and the battleship—but a few months ago relegated to the scrap heap—has come into its own once more.

So it will be with the tractor. It will make trenches untenable and thus its importance becomes inestimable indeed, for it will put the men in the field, *where they belong*, not in the trench scrap heap. No war can ever be won if the men stay in the trenches. If there had been no trenches the European war would have been over in six months.

THE ELECTRO GYRO-CRUISER.

(*Continued from page* 543.)

mor of (h), serves double purpose as armor and as the bearing seat and guide for a system of huge ball bearings; (m) is a ball bearing five feet in diameter and probably of solid steel; (m) and its fellows roll in the space between (1) and (l).

This system of bearings will be able to carry a weight of thousands of tons at a rotation speed of 60 miles an hour—which would be only 30 miles an hour between the ball and either one of the bearing surfaces—with minimum friction, wear and trouble, and with the maximum reliability of any system which may be devised, even as it is so with more modest types of ball bearings.

(n) is a section of the armature res of the very powerful two-speed electric driving motors. The two multi-polar motors are each about 70 feet in diameter. On low speed they will be able to force the gyro-cruiser over rough country and directly up steep grades, while very steep grades will be overcome by a zigzag ascent. On high speed the twin motors will be able to rotate the great wheel at 15 or 16 revolutions per minute, a rate at which the cruiser will be making 60 miles an hour over the road.

(o) is an armature coil; (p) is a field coil; (q) is the field core; (r) is the commutator; (s) is a brush which plays between the commutator and the slip rings (t).

The brushes are mounted on miniature electric trucks which run upon a circular track laid inside of the commutator, and their velocity of movement over the track, as well as their position at any time, is controlled from the bridge. The significance of this method of control may be seen upon a little reflection.

(t) slip rings mentioned; (u) is the space in which is the commutator controlling the rotating magnetic fields of the liquid gyroscope; (v) feeders running from gen-

Brilliant Light in a Jiffy

Everybody appreciates the value of Franco Flashlights. Around the home at night; motoring; out-of-doors; for boy scouts; mechanics; farmers and postmen, Franco Flashlights are indispensable. At a pressure of the finger they throw a brilliant stream of white light just where you want it.

Franco FRANCO **Flashlights**

are guaranteed absolutely to give you worthwhile service and satisfaction. The Radio Battery inside is the finest flashlight battery produced, will give more light and last longer. *At the Panama Pacific Exposition Franco Flashlights were awarded highest honors—Gold Medal and Blue Ribbon.*

Flashlight illustrated is 5½ inches long, fibre covered, nickel trimmings and will throw light a long distance. Patented "Wireless" feature prevents short-circuiting when in contact with metal. Complete with Radio Battery and Tungsten Lamp, at $1.00; everywhere.

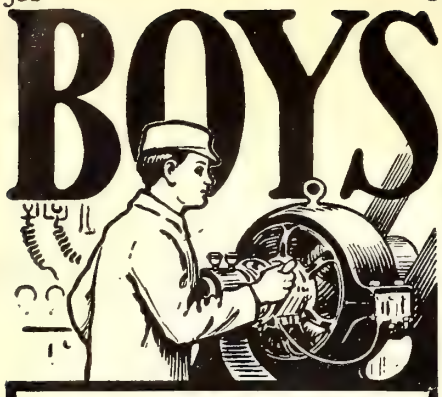
FRED. R. HEILMAN
444 Niagara St. Buffalo, N. Y.



erator to motors; (w) brushes taking current from the slip rings (x); (x) slip rings; (y) feeders from the brushes (z) to the slip rings (x); (z) brushes taking current from the generator's commutator; (Z) commutator of the generator; (Y) armature of the generator; (X) field coil; (W) field core; (V) is the shaft direct connecting the 40,000 horsepower generator to the 60,000 horsepower Diesel engine; (U) bearings; (T) crank case of the engine; (S) cylinders; (R) exhaust; (Q) oil and water intake pipes; (P) partitions and fuel storage tanks; (O) is a passage between the fixed and the rotating structures.

Despite the rotation of the great wheel the engineers' force will have their regular stations. Provision will be made for the protection and comfort of the men who must work in this structure. The rotation will be at the maximum very slow, as we have seen; and it is thought necessary or very desirable that as much of the weight of the gyro-cruiser as may be possible be carried inside and as a part of the great wheel.

(N) is a girder and part of the wheel's framed structure; (M') is also a part of the framed structure. (M) provides additional space for fuel and water tanks and various other storage. In the unmarked spaces of the fixed structure—outside the broken line—will be yet other storage spaces and rooms devoted to crews' quarters and to the thousand and one other incidentals of a giant fighting machine; (L) is a man on tiptoes and arm extended to the foot of the machine. This shows the comparative size. It may here be noted how the sharp foot of the wheel cuts into the earth. This cutting power will be the only "springs" which the gyro-cruiser will need. The bevel and shape of the foot will be a matter of nice calculation and much experimenting to determine the design best combining for an average soil the maximum cushioning effect of the cutting act with the minimum practicable friction between the wheel and the cut.

(K) 50-foot tree shown for comparison; (J) a barbed wire entanglement which, in this case, might as well be made of cobweb; (I) rampart; (H) is a trench with its machine gun helpless and silent to this foe.

We will now consider the liquid gyroscope, the detail, longitudinal section of which is shown in Fig. 3. We will not argue with you as to whether or not it may be possible to construct a solid gyroscope of 2,000 tons weight, or as to whether or not it may be practicable to divide that weight among a number of smaller wheels. We do not think that the one is possible or that the other is practicable, but we will allow anyone his own belief. The first governing condition with which we are met is that the mass of our gyroscope must be driven at an average circumferential velocity of some figure between three and eight miles a minute. Taking eight miles per minute, or 704 feet per second, as a maximum velocity and allowing 40 feet as the average distance from the axis of rotation to the rotating mass, we find that the maximum centrifugal force or bursting effort of the 2,000-ton gyroscope will be 770,500 tons. At a circumferential velocity of three miles per minute the burtsing effort will be 36,200 tons.. It is probable that the gyroscope will not need to be operated at a much greater velocity than three miles per minute, in which case 500 tons of steel in the armored rim (h) would be fully able to take care of the bursting effort. But even if velocities approaching eight miles per minute were found desirable 10,000 tons of steel—elastic limit of 15 tons per square inch—would suffice. This last

Big Money in Electricity

The electrical industries offer wonderful opportunities for boys with a liking for electricity. The salaries paid to trained men are large—promotion comes rapidly, and, best of all, the profession is not overcrowded.

The opening of new lines, from time to time, (such as wireless telegraphy and telephony), promise attractive and paying fields to those who wish to specialize. The *will to do* and *Special Training* will bring success to you.

The International Correspondence Schools of Scranton can help to make you an expert in electrical work. Hundreds of boys have already won success through I. C. S. help. You can do the same. Everything is made so clear that you can learn in your spare time, regardless of where you live or what you do. No books to buy.

There's big money in electricity. Get after it by marking and mailing the attached coupon today. Finding out costs you nothing.

case would give a cross sectional area of steel in (h) of 100 square feet, which is the area of a triangle, 20 feet at the base and 10 feet in height. These figures reveal the limits within which we must work.

Referring again to the diagram, Fig. 3, we have a circular tube—diameter 100 feet over all by 25-foot cross section—bounded on the outside by the iron case (A) and lined within with non-magnetic steel sheeting (B). (i_1) represents iron rings serving as pole pieces for the magnet coils lying between them. (i_2) indicates spaces in which are wound the large magnet coils encircling the sheath (B). (j_1) is a spiral of non-magnetic steel, and which makes six turns around the inside of the tube in making one circuit. (j_2) is a second spiral which is set one-half turn in advance of (j_1). These spiral guides cause the liquid, when making one circuit around he primary axis of the tube, to make six turns about the secondary axis—which is a circle and is the line joining the centers of cross sections of the tube. (k) are 12 balls of hollow iron shell and structural steel core construction. Each ball is 15 feet in diameter, weighs about 40 tons and has about 10 tons of buoyancy. The balls are held in their relative positions by the magnetic fields of the coils (i_2). Thus, due to these coils, we should find a north magnetic pole between the first ball (k) and the next ball to the left of (k), a south pole between ball No. 2 and ball No. 3, north pole between ball No. 3 and ball No. 4, etc. The liquid to be first employed will be water, although hot, liquid-fusing metals may be later employed, or mercury—if we ever penetrate to the more plentiful deposits of that useful metal which quite likely lie deeper down in the earth's dense bosom. Almost exactly 2,000 tons of water will be carried in this particular gyroscope. This mass will be whirled by the rotating magnetic fields of the coils of (i_2) sucking with them, as they rotate, their armatures, the balls (k). The magnetic rotations will be controlled by the commutator (u) of Fig. 2. Balls (k) will be prevented from coming in contact with the walls of the tube by the centripetal effect upon them of the spiraling motion given to the water by the guides (j_1) and (j_2). This effect is as simple as the parallel effect in a cream separator, that the light c eam goes to the inside, while the heavy milk whirls to the outside. By impressing the spiraling motion upon the water the light, buoyant balls will be held with a great force to the center line of the tube, where, surrounded on all sides by water, they may be sucked by the rotating field at high speed around and around the great circuit with-

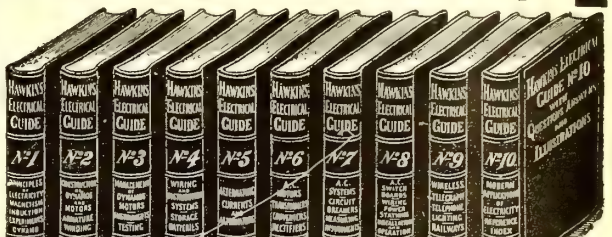
Do It Electrically



The applications of electricity are increasing every day. The man who has an exact knowledge of electrical science has ever growing opportunity for profit. Ten years ago practically all machines in use were run by steam engine and countershaft. Statistics now show that most of the machines used are now operated by the electric drive. A generation ago gas was the only known means for lighting and cooking. Now almost every modern house is lighted by electricity, and electric cooking utensils are coming more and more in use. Even the steam locomotive, that great achievement of the twentieth century, is being gradually replaced by electric power. Whether it be for driving machines, for railway transportation, for lighting, for heating, for cooking, for a thousand daily necessities, the watchword of the age is "Do It Electrically."

Hawkins Electrical Guides Will Show You How

Electrical knowledge means money to you and these books will show you how to get it. Hawkins Electrical Guides are the standard works on Electricity. They cover every single phase of the subject and they are written in a way you can understand. The text matter is arranged in questions and answers, and contains several thousand illustrations. No more groping for a solution of your electrical problem. You find the answer at once, clearly and concisely.

A Most Complete Library of Electricity at the Lowest Cost

Look at the titles and convince yourself that Hawkins Electrical Guides tell you everything you want to know in Electricity. They are a complete course in Electrical engineering, written especially for the ambitious man who is training himself for advancement, for the wide awake man who is likely to be called in for work outside of his regular line, for the man who needs at his elbow, for ready reference, an accurate up-to-date work on electricity. An examination of these books will convince you of their value instantly. They cost $1 per volume. They are a wonderful buy at this price, and they are the best electrical books at any price. Don't take our word for their merits. Fill out the coupon today and the books will be sent you absolutely **FREE** for your own examination. You have seven days full use before you pay a cent.

In Handy Separate Volumes The binding is in flexible black leather with gold edges—very durable and attractive. The books are easy to handle and easy to read. They fit your pocket and your pocket-book as well.

Shipped to You FREE

Send no money. Examine the books first. Decide for yourself that they are the most complete library of electricity ever published, and that you cannot afford to be without them. Every book is complete in itself. The price is only $1 per copy, but the complete set is the best bargain. Settlement can be made at only $1 per month. EIGHT NUMBERS ARE READY.

A FEW OF THE SUBJECTS

Magnetism—Induction—Experiments—Dynamos—Electric Machinery—Motors—Armatures—Armature Windings—Installing of Dynamos—Electrical Instrument Testing—Practical Management of Dynamos and Motors—Distribution Systems—Wiring—Wiring Diagrams—Sign Flashers—Storage Batteries—Principles of Alternating Currents and Alternators—Alternating Current Motors—Transformers—Converters—Rectifiers—Alternating Current Systems—Circuit Breakers—Measuring Instruments—Switch Boards—Wiring—Power Stations—Installing—Telephone—Telegraph—Wireless—Bells—Lighting—Railways. Also many Modern Practical Applications of Electricity and Ready Reference Index of the 10 numbers.

Easy Payments

Accept this great offer now—today. Each page—every illustration will convince you of the big value we are offering. See the books first, then decide. If you decide to keep them you can make settlement at only $1 monthly until paid for.

out suffering or causing any harm and without the gyroscope encountering any friction except the friction of a liquid flowing through a large tube, which, though by no means small, is, fortunately, not of the same order as the friction between a vessel moving in the sea and the water which it passes. This spiraling scheme is the crucial point of the whole idea and is the one thing which raises it from an idle dream to the plausibility and the possibility which it is.

So, in type at least, shall the monsters of the future be created and be set loose upon the land. These giants of a race of toiling machinery will take their places in the trenches which are the valleys, and behind the ramparts which are the hills, and one more freedom will be added to the roll of emancipation and will come out from the nation which loved humanity.

MYSTERIES OF MATTER.

(*Continued from page 549.*)

test state, it is at its lowest point in the scale of evolution, and progress depends on a fall of temperature by radiation. Lockyer's inorganic evolution, joined to the nebular hypothesis, and this to geological and biological evolution, completes the evolutionary cycle of matter to its present terrestrial stage.

We now come to the most interesting, most marvelous mystery of matter. There has been collected a wealth of evidence which proves that the atom is an organized planetary system of dazzling complexity, in which electrons simulate the movements of the planets of our solar system. The negative electrons of the atom swing around the positive nucleus, like planets around the sun. The planet Neptune requires 165 years for a single revolution around the sun, but it has not made a half revolution since its discovery, while the electrons of the atom complete their revolutions around their central nucleus in a millionth or a billionth of a second. The electrons revolve in a series of concentric orbits all in the same plane. While the larger part of the mass appears to reside in the nucleus, the nucleus is relatively minute, with a diameter of probably less than 1/5000 of that of an atom. It is thought that the simpler atoms, such as hydrogen, nebulium and protofluorine, where the electrons are few, all revolve in one ring, but in the heavier and more complex atoms their orbits lie in three to five, or more rings. The atom is as much a machine as an electric motor, and both are electro-magnetic engines.

Nearly the whole mass of the atom resides in the nucleus, but the nucleus is relatively very minute. It is quite impossible to imagine the extreme density of the nuclei. If an oxygen nucleus could be enlarged to a diameter of one inch, its mass would probably be more than 500 tons. If oxygen gas, at atmosphere pressure, could be magnified until the nuclei were each equal to the mass of the sun, we would have the sidereal universe reproduced in which the mean distance between atoms would approximate the mean distance between the fixed stars of the universe. Since the atomic weight of oxygen is sixteen, the atom is supposed to have eight electrons revolving around its nucleus. If we apply the same analogy of magnification to the structure of the oxygen atom, we would have a system of eight satellites in which the relative distances between the revolving electrons and the central nucleus would approximate the distances of the eight planets from the sun. Thus in oxygen gas, the sidereal universe, with its stars and revolving planets, is reproduced in miniature.

It will be seen that the structure of gases

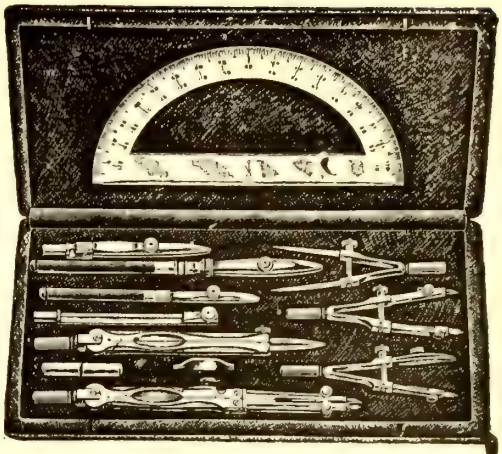
counterfeit on a very small scale, the structure of the great sidereal universe. Since all the forces acting in the nuclear atom are electrical, may not the forces acting in the stellar universe be electrical? Is not the force of universal gravitation electrical? Should not the universality of law lead us to infer that the force of gravitation is an electro-magnetic force?



It will be seen from the preceding description that the form of the atom is that of a flat disc, which probably possesses elasticity. It was formerly supposed that atoms were spheres of infinite hardness, and of course without elasticity. The atom, and in fact all matter, is immersed in a medium called ether, which is continuous, frictionless and pervades all space. Ether is the universal carrier of the energy of light, heat, electricity and X-rays. Hydrogen has been called the smallest and lightest of the elements, but the sun, stars and nebulas yield still smaller atoms, called proto-hydrogen, asterium and nebulium. The atoms of these very primitive forms of matter are simpler in their arrangement, and easier to calculate than most terrestrial elements. Working in the dark, the alchemist of the Middle Ages attempted the transmutation of metals, without even knowing the nature of his problem. Science has now unveiled the secret of transmutation, by observing nature's process of changing the heaviest element into a series of different products. The alchemist vainly sought to change mercury into gold. We now know that mercury might be changed into gold, if we could expel from its atoms one alpha particle, and a beta particle; or if the metal thallium could be made to expel an alpha particle, it would become like atoms of gold. This has not yet been done but it is possible that it might be done by the application of an electric current of some million volts.

The principal weight of the atom lies in its nucleus, but the nucleus is very small compared with the size of the atom. It contains so-called "sub-atoms" and electrons, in association with positive electricity. The electric charge of the nucleus is therefore overwhelmingly positive. In the breaking up of atoms by radio-activity, the alpha particles (helium atoms) and the beta particles (electrons) are thrown off from the nucleus. In the outer region of the atom there is a sufficient number of negative electrons to balance the central positive charge. It is this outer region that controls the chemical, and much of the physical influence of the atom. It will thus be seen that the radio-active charge is connected with the nucleus, while chemical and electro-chemical properties are controlled by the outer rings of electrons. It is now known that there are relatively few electrons revolving around the nucleus, probably not more than half of the number representing its atomic weight, in which hydrogen is the unit.

The period of revolution around the nucleus, by the electrons, appears to be identical with Kepler's harmonic law of planetary motion, in which electrical force, varying inversely as the square of the distance, takes the place of the force of gravitation. The lightest atom is supposed to have but one revolving electron. This limits the smallness of the atom, because you could not have an atom with no revolving electron. The smallest atom resembles the earth with its one satellite. The heavy atoms have far greater numbers; an atom of mercury would possess a hundred electrons, which is ten times as many satellites as Saturn has.

Lockyer has shown that the younger and hotter stars contain elements fewer in number, and simpler in structure, than the

Free!

Complete Set of Drawing Instruments

YES, I will give you this complete set of drawing instrutments absolutely free. They are regular working instruments—the kind I use myself and they do not cost you a penny. And besides the instruments in this exquisite plush lined leather case, I will give you absolutely free a 20x25 inch drawing board, a 24 inch T-square, a 12 in rule, a supply of drawing paper, two triangles, a French curve, pencils, erasers, thumb tacks, etc., etc. A complete draftsman's working outfit. And I give it to the men who get my personal instruction absolutely free.

Be a Draftsman!

Draw $125.00 to $175.00 Per Month

There is an urgent demand for skilled draftsmen. Companies are issuing calls every day for men to fill positions paying from $125.00 to $175.00 per month. Work is light, pleasant and profitable.

Chief Draftsman Will Instruct You Personally

Pay as You Wish!

WHAT I want is the *right kind* of men. Don't bother about the expense. I charge a very small fee for training you to be an experienced draftsman. You can pay the small cost as suits you best. My object is to develop expert draftsmen.

I am Chief Draftsman of a large and well known firm. I have been doing the highest paying expert drafting work for a quarter of a century and I know the kind of training that is demanded from the men who get the big salaries. I will give you personal instruction, deal individually with you and give you up-to-date, practical working plans just as your ability and advancement require. I train you by giving you actual work—practical work, the kind that you must be able to do in order to hold permanent, big paying positions. I will give you my indivdual instruction. If your work is right, I will advance you rapidly. If it is wrong, I will show you where, and make you do it right, and do all I can to make you an expert draftsman and designer in a short time. *Write today without fail.*

Send Coupon For My Big New Book

Put your name and address on the free coupon or a letter or a post card and send it to me today. I will send you absolutely free and prepaid my new book "Successful Draftsmanship," and the great special offer that I am now making on which you get the $15.00 Draftsman's Working Outfit absolutely free. You assume no obligations of any kind in sending in the coupon. Get in line now for a big paying position. Getting the book and full particulars of the special offer is the first step.

Here's *YOUR* Chance to Learn
DRAFTING
This Complete $15 Drawing Outfit and Full Instructions in Mechanical Drawing **FREE**

There's a good job waiting for you. The country is facing greater prosperity than it has ever before experienced. Far-seeing men are getting ready for boom times. Get this training now and share in the coming prosperity. We make the way plain.

CHARLES W. MOREY
President of the College and Head of a Large Chicago Firm of Civil, Mechanical and Electrical Engineers and Contractors.

Men Wanted AT BIG SALARIES

This is a rare chance for a few wide-awake young men.

On account of the rapidly increasing demand for trained draftsmen Pres. Morey has issued orders that instructions be furnished to a limited number of young men who are inclined along engineering or architectural lines. Read about this great offer below—then mark and mail the coupon.

STUDY AT HOME Devote your spare hours for a short time only and learn this profitable and pleasant profession, and get in the class drawing the big pay envelope. Hundreds of men are in daily attendance at this old established college. In your own home you can do the same work these men are doing, and the same experts that teach them will guide you toward the big job. These well-known engineers prepare your instruction matter. Your work is examined and approved by them. They know exactly the **practical training** you need and **they** train you. No books to sell. Live, up-to-date blue prints of work in actual construction. In your own home you work with plans of machinery, buildings, steel works, etc., actually being constructed in Chicago, New York and other large cities.

Electrical Drafting and Design

No other similar correspondence course in America has a resident college of National reputation back of it, nor a faculty of active experts actually engaged in municipal and corporation engineering work. These men know exactly the kind of training you need because they are in constant charge of big work.

$45 COURSE FREE IN MECHANICAL DRAWING

This College has set aside a limited number of Free Scholarships and will give the regular **$45 Course in Mechanical Drawing Free** with any one of the Home Study Courses named in the coupon below—**this is in addition to the complete $15 Drawing Outfit** which is also furnished to students free. Take advantage of this unusually liberal offer today, as it will be withdrawn when the allotted number of Free Scholarships has been awarded. It costs you nothing to get full information. No obligation on you.

older and cooler stars. In this fact we face the gigantic evolution of matter from the primitive source of the universal ether, to the complexity of terrestrial organic matter. The mighty machinery of the cosmos is immortal in its operation. Ceaseless change is the only constant thing in nature. The complete cycle of change leads matter through all its phases from the simplicity of the hottest star to the complexity of matter in the planets and in our cool earth.

A recent article by O. Lehmann, on the discovery of the formation of liquid crystals, incidentally confirms the theory, that atoms are flat and not spherical. He assumes that the molecules of these crystals are tiny flat plates whose surfaces are perpendicular to the optical axis. He says, "The molecules easily glide over one another in a direction parallel to their flat surfaces," and concludes that the crystals are combinations of plate-like molecules. Since molecules are small groups of atoms, and some molecules consist of single atoms, it follows that disc-shaped atoms would lend themselves to the formation of flat molecules.

It is probable that the atom is elastic; not perhaps by the pressure that could be secured artificially in the laboratory, but by the gigantic gravitational pressure of the interior of the planets and stars. The earth's interior is so hot that if its pressure were released it would explode into gases of very high temperature. The pressure of gravitation near the earth's center amounts to millions of pounds to the square inch, and there matter is reduced to the density of platinum. Under this force liquids yield like a sponge. Owing to the enormous pressure that gravitation imposes on the earth it is compacted into a dense mass as rigid as that of a ball made from nickel steel armor plate.

We now appear to be on the verge of further discoveries in the nature of matter which may lead to a knowledge of the mysterious, unknown, ether. All intelligent people are interested in new information regarding the swift electrons that light our cities, propel our street cars, operate factories, transmit speech, carry wireless messages and serve man in hundreds of ways. A host of eminent scientists have framed a science of radio-activity which has changed the entire theory of matter, involving conceptions that are difficult to explain to those who have not specialized in physical science. Even the accomplished physicist, Sir William Crookes, says that the conceptions of atomic physics are often hard to understand. We are unfortunately lacking in gifted interpreters of physical science, such as the nineteenth century furnished. Darwin, Huxley, Spencer and Tyndall could clearly explain to the uninitiated, in simple words, the most intricate scientific discoveries of their period.—*Popular Astronomy.*

LATEST DE FOREST RADIO APPARATUS.

(*Continued from page 557.*)

nect the high voltage battery to the binding post marked B B. This scheme has another advantage over the old method, for the experimenter may place any voltage across his instrument and vary it by merely operating the switch handle of the potentiometer. A rheostat for regulating the current supplied to the filament is enclosed in the cabinet and is regulated by turning a rubber handle shown on the right of the cabinet. This is something new for the amateur who is interested in audion detector sets.

An instrument for which the amateur "wireless bug" has long been looking is the recording relay, depicted at Fig. 2. which will operate a sounder, tape recorder and a bell by the regular incoming wireless messages. This consists of an ordinary sensitive voltmeter movement which comprises a strong, permanent magnet in which an armature B is placed between the two field poles C C. The armature B is delicately supported in jewels and carries a contact arm D for making connection with terminal E when it is in operation. The recording or ringing instrument is connected in series with the terminals D and E and a source of current, such as batteries, etc., while the armature B is hooked up with the receiving set in place of the regular 'phones.

The operation of this relay is very simple and the explanation is as follows: As soon as a radio message is received the armature B is deflected or turned and in so doing the arm D will make contact with terminal E, which will complete the circuit of the recording device. Although this device can be used with any sensitive detector, it will work better with an audion and better still with an audion amplifier. It should also be understood that this instrument cannot be employed where high speed messages are to be received. As the period of oscillation is very large it is impracticable to use this instrument for high speed messages, but it can be successfully employed for calling purposes, etc., that is, to announce to the operator that someone wants him.

THE DUBILIER MULTIPLE MUSICAL TONE RADIO SYSTEM.

(*Continued from page 559.*)

on oscillator b. Fig. 3 shows the complete circuit, where q is a quenched cap, C^3 the high tension condenser and 1^1 1^2 oscillation transformer.

The apparatus operating on the above principle is shown in Fig. 4. The oscillation transformer is placed upon the back of the cover of the case as perceived. The gap A is of the quenched type and is constructed of silver and copper bar electrodes. The mechanical vibrator B is used for charging the condenser of the oscillating circuit; the current used by the interrupter is regulated by rheostat C, and the amount recorded by the ammeter D. The high frequency aerial current is read by the hot wire ammeter E. The oscillating circuit is controlled by the condenser enclosed within the case and same is regulated by the handle F. The current is interrupted by a telegraph key located on the top of the shelf, as seen. This outfit is operated on 110 volts D.C. supplied either from a storage battery or a dynamo. The complete outfit weighs 32 pounds, which is marvelously light as compared with any other similar type of apparatus now available. The set illustrated at Fig. 4 is of the pattern used on the French military aeroplanes. The British government is also using radio apparatus of the Dubilier type extensively. They appear to mark a new era in radio transmitting set design, at least where small or medium size outfits are required of the minimum volume and weight.

SEATTLE HEARS RADIO FROM MEDITERRANEAN.

A Seattle dispatch says that a wireless operator there has been able to hear distinctly for several days Italian warships in the Mediterranean talking to one another. He heard the cruiser *Etruria* calling the battleship *Carlo Alberto.* "We hear the Government radio at Arlington every night," said the operator, "and are able to listen in on radiophone calls to San Francisco. We frequently hear radio calls from Japan, Russia and Germany."

HYPNOTISM!

Be a HYPNOTIST and MAKE FUN and MONEY!

It takes but a few hours to learn. The study is both easy and fascinating. Hypnotism is an endless source of fun and wonder. If you know how to Hypnotize you can perform some of the most marvelous feats imaginable. You can do a hundred amazing things that other people cannot do. You can surprise your friends and make yourself popular. You can place others under this strange and mystic spell. You can compel them to think, act and feel just as you wish. If you want to **make money** you can do so by giving entertainments, treating diseases or teaching the art to others. Why work for others, when you may master this money-making profession so easily? Investigate **NOW!** You may learn at your own home. I will send you my **free treatise** for the asking. It tells you about Hypnotism and how you may easily learn it. It is profusely illustrated and is written in a simple style easily understood by all. Anybody may learn from it of how the Hypnotic Spell sways the will of its subjects, heals the sick, reforms the degraded, overcomes bashfulness, helps to trade or position, amuses an audience for profit, and gains for the operator himself courage, will-power, and a means to health, wealth and happiness. It also treats fully on Personal Magnetism and kindred subjects. Remember, this treatise **is absolutely free.** Simply write for it, and it will be sent by next mail, all charges paid. Don't send any money or stamp, but send your name and address **today.** Address:

THE SHIRIKARI TENTACLE.

(*Continued from page 555.*)

without censorship. I wasn't held as close as that, but I know that I never went from one street to another without being dogged by spies, and every letter I wrote or received was read.

"Then came the line-up with Mexico and the war. I at once demanded a settlement and passports and they smiled and said: 'Certainly'—in Jap, you know. That night I was doped and the next day I woke up on board that ship out there—the *A atusa.*"

"What!" exploded the Admiral. "That vessel aground on the Chulavis Bar?"

Forsythe nodded as he drew into a spasm of recollection.

"Yes! Her Captain is a renegade 'No Country' man and the crew are the same. They are paid by the Japs to handle the Tentacles and they loaded sugar at Manila as a blind and then ran her in here with an alleged crippled engine and put her on the bar."

The Admiral turned to one of his officers and growled hoarsely: "Go back to the ship, sir, and signal every vessel in the bay to train its guns on that *Aratusa.* Then take a party over in the launch and demand surrender. Instantly, Mr. Stevens!"

Forsythe's eyes gleamed and he went on: "The Japs had put me on board to see that the devilish things were handled right, and they tortured me into doing it. See that!"

He held up his hands, the thumbs of which were crushed and distorted out of any recognition if they hadn't been on the hands. Cawthorne ejaculated with horror: "Thumbscrews?"

Forsythe nodded. "They starved me at first when I refused to help them in any way. Then they used the screws and I had to give up—I had to! That Captain is a devil, incarnate, among devils as bad as himself!"

"That ship is driven by turbo-generators—that's why the Japs bought her. They can work up to twenty thousand volts if they want to. The winding is very peculiar, after the wonderful Haye-Abbot system, and the current it makes has action and qualities different to anything known before. You'll see all that if you get onto that ship."

"But how did they transmit it, Forsythe?" muttered the Admiral, impatiently.

"Tiny submarines!" groaned the man. "My special invention. They run out with a fine composite wire cable through which they are directed and through which that current is shot after they fasten onto their prey. They're not over four feet long and a man can carry one of them. In the head of each is an electro-magnet with pull enough to hold onto a steel hull. Then the high voltage Haye-Abbot current is switched in; runs through the vessel and back through the air, by wireless—the wonderful Swartson antenna, a bit developed."

He groaned in weakness and pain, but in a few moments he rallied and continued: "You'll find 'em on board—all the stuff. That vessel has a double sheathing, you know; partly used for water ballast, and there's thirty of those Tentacles stowed away in those tanks. That's why the port authorities who came aboard after the accursed captain had run her aground didn't see anything suspicious. They didn't see me, anyway, for I was bound and gagged and stowed in one of those tanks."

He sank back on the cot, gasping. The doctor gave him some stimulant and presently he said: "They ran her on the bar so that they'd have an excuse for running their engines. Claimed they had a bad leak and had to pump. When any outsiders came aboard

11 Lessons of Course In Drugless Healing FREE!

Positively and absolutely free to you! Not one cent to pay now or later. To a limited number and for a short time only, we are giving 11 Complete Lessons in Mechano-Therapy absolutely free. There is no cost to you at all for these 11 complete lessons. **But you must act quick!** This remarkable offer is strictly limited As soon as a certain number of these sets of 11 lessons have been given we shall withdraw the offer. Don't wait a minute. Act now.

These Lessons Teach You

How to Treat Headache	How to Treat Catarrh
How to Treat Neuralgia	How to Treat Epilepsy
How to Treat Constipation	How to Treat Hay Fever
How to Treat Indigestion	How to Treat Paralysis
How to Treat a Sprain	How to Treat Pleurisy
How to Treat Dyspepsia	How to Treat Asthma
How to Treat Rheumatism	How to Treat Gout
How to Treat Lumbago	How to Treat Jaundice

Why We Make this Great Offer

We want the public to know the **real truth** about drugless healing. We want you to convince yourself by an actual and practical demonstration just what a marvelous curative force may be placed at your command We want you to see for yourself what tremendous opportunities have been opened to practitioners of Mechano-Therapy. You will see what has been done. You will see what can be done—by you! A Diploma in Mechano-Therapy offers you a profession of dignity, prestige, influence and wealth. No special training or experience needed. If you are ambitious and can read, the way to success is open to you. Take advantage of this lifetime opportunity.

Also Free! $15.00 Set of Eight Anatomical Charts

Each chart 30½x22 inches, lithographed in many colors. Shows 70 diagrammed illustrations of different organs and parts of the anatomy. Regular $15.00 set of charts. Now also free for a limited time only.

New Illustrated Book on Drugless Healing FREE

Thousands of Mechano-Therapists throughout the United States are making a big success. Let us tell you about them. Let us prove how you can easily make $200 to **$500 per month** and more. Write while this special 11 free lessons offer is open. Send free Coupon or your name and address on postal today, and receive, free, beautiful Colored Anatomical Chart, new illustrated Book on Drugless Healing which makes everything clear.

American College of Mechano-Therapy Dept. 500 81 W. Randolph Street, Chicago, Ill.

Could You Fill His Shoes?

SUPPOSE a good job were open where you work. Could *you* fill it? Could you jump right in and make good, or would the boss have to pass you up because you lacked *training?*

The man who is offered the big job is the man who has trained himself to hold it *before* it is offered to him.

Don't *take chances* on being promoted, don't *gamble* on making good when your opportunity comes. If you want a big job that carries responsibility and pays good money, *get ready for it.*

Pick out the job you want in the work you like best. Then start *right now* to get, through the International Correspondence Schools, the *training* that will prepare you to hold it.

Thousands of men have advanced through I. C. S. training to the very jobs they wanted most. What these men have done *you* can do. All the I. C. S. asks is the chance to help you. No matter where you live, the I. C. S. will come to you and train you in your spare time in your own home.

The job you want is within your reach. I. C. S. training will win it for you. The thing to do now is make your start. Mark the attached coupon and get it into the mail. Don't let a moment waste. Here's the coupon—mark and mail it now.

they were operating pumps; when they were treating your vessels they were operating the generators. You couldn't tell out there, a mile or more away, what they were doing."

"How did you escape?" murmured Cawthorne, his voice and eyes filled with sympathy.

"It was last night, or sometime—I don't just know when. They were planning a night attack on one of your ships and I was forced to direct the adjustment of the little submerging tank of the Tentacle. They were slipping it overboard and I saw a chance to slip, too; and I did. I managed to swim through those breakers and got ashore, with a boat right behind me. Then I scrambled up to the shore road and just as an auto came along I fainted. Woke up here in the hospital."

The boom of a gun came from over the bay. The Admiral exclaimed: "My God! If they fire on that ship they'll destroy all that we ought to see. Come, gentlemen! We must go back."

A shot had been fired over the *Aratusa* as a demonstration of real business, but the launch sent over to take possession was not resisted in any way. The Captain and crew had taken to the boats and dashed ashore, and the Lieutenant went aboard a deserted ship.

* * * * * * * *

Everything was found as Forsythe had stated. In the tanks were stowed twenty-three of the curious little Tentacles, which on being opened and examined showed marvelously ingenious mechanism and just as marvelous workmanship. The salient feature was the control disc, which Kilroth instantly recognized as a perfection of Marvin's invention, but never before put into practical use.

In the report sent to Washington the description of the astounding Tentacles was briefly as follows:

"It is propelled by a moderate current through the attaching wire conductor, a marvel of strength and transmission qualities, but the composition of which has not yet been determined. The submerging tank holds the Tentacle at apparently any desired depth, and the aluminum floats attached to the conductor also holds that at the required depth, taking the weight off the Tentacle and requiring only traction power. A device of amazing electro-mechanism provides that if the wire conductor is broken at any point a clipper cuts that wire close to the Tentacle, and at the same time an inlet valve is opened into the submerging tank and the Tentacle sinks to the bottom of the ocean. This means that the discovery of any one of these Tentacles is avoided by the simple expedient of severing the wire at the tender—the *Aratusa*—and the Tentacle instantly sinks from any detection. The short length first discovered had been broken by some accident—probably contact with one of our submarines—and was instantly clipped off at the Tentacle, which now lies at the bottom of the bay.

The *Aratusa* must have sunk—perhaps to escape detection—seven of these Tentacles, in its week of operation in this bay, for Forsythe states that thirty were on board and only twenty-three remain. This man—the inventor—also states that the return of the current through the air was by special construction of the wireless telegraph antenna of the *Aratusa,* which received the return current from the smoke-stacks or fighting masts of the vessel that the Tentacle was attached to.

"It is respectfully suggested that an acknowledgment be made by the Naval Board, or by the President, of appreciation of the inventor. Forsythe's disclosure of this terribly effective weapon. His distress at his inadvertent work with the Japanese while they were on friendly terms with us, resulting in his tortured compulsion to continue that work against his own country, will surely result in death unless he is, in some way, comforted."

* * * * * * * *

THE MARVELS OF MODERN PHYSICS.

(*Continued from page* 556.)

the number in a stream of such particles and measuring the charge of the total number; then, by division, he obtained the charge of a single particle.

The late M. Curie and others believed that those particles in some way form an elemental magnet, which they have termed the *magneton,* and so the field, instead of being exhausted, is just opening up and scientists see ahead of them explanations of many of the old puzzling questions concerning electricity, light, matter and energy.

The foregoing experiments only serve to illustrate what is really happening in the scientific world and how progress is continual, though striking inventions may only come at intervals. Marvelous as the results already achieved seem, they are only the beginnings of greater marvels the future has in store for us.

RADIO AND ELECTRICAL ENGINEERS MEET AT 'FRISCO.

At the Panama-Pacific convention of the American Institute of Electrical Engineers, held at San Francisco, Cal., two of the sessions were joint sessions with the Institute of Radio Engineers. The first of these was held on Thursday afternoon, September 16, in the building of the Native Sons of the Golden West, R. B. Wolverton presiding.

A paper by Harris J. Ryan and Roland G. Marx, entitled "Sustained Radio-Frequency High-Voltage Discharges," was presented by Professor Ryan.

This paper described experiments made upon discharges in air at 60 cycles and at 88,000 and 188,000 cycles per second. The experiments included discharges from a single electrode, between a blunt point and plate, and the corona about a wire. Diagrams of the apparatus and photographs of the discharges were included. A sphere gap was used for measuring voltage. The ability of the radio-frequency brush to produce thermionic conduction through glass, porcelain, quartz, etc., was found to be its most remarkable property. The application of high voltage at high frequency to a porcelain insulator was found to produce hot conducting cores in the porcelain. No insulation supporting a conductor under such conditions can endure unless so designed that no air in contact with it is overstressed. The eyclograph was used to measure energy and power-factor. The following conclusions are reached:

Sustained radio-frequency corona brushes or flames once started are maintained at much lower voltages than those required to start them by overstressing and ionizing the atmosphere. They quickly destroy even the most refractory insulations by their heating and ionizing properties. The power-factor of the charging current of a conductor in corona due to the application of sustained radio-frequency high voltage is decidedly lower than the corresponding power-factor at low frequencies. Nevertheless, because of the high values of the currents that produce the radio-frequency coronas, the losses they cause may be hundreds of times the corresponding low-frequency losses.

THE WAR AND PROGRESS IN RADIOMECHANICS.

The war has led to a considerable development of radiomechanics. Among the things claimed for it is the ability to blow up the magazines of warships, to steer torpedoes in water, to drop torpedoes from airships and steer them to a goal on land, and to blow up bridges and fortresses.

To obtain a rational opinion on the question, the *Petit Parisien* asked for a statement from Prof. Branly. Prof. Branly, who is a Catholic priest, is known to scientists and students throughout the world. He is one of the men to whom the success of wireless telegraphy is due.

"It is possible to produce at a distance mechanical effort of any kind, but it is always necessary that the object to be affected be provided with apparatus receptive of electric waves. It would consequently be possible by means of radiomechanics to blow up at a distance a bridge or a fortress if the object to be destroyed were previously equipped for the purpose; that is, if it were fitted with a special apparatus. The consequent difficulties that supervene it would be superfluous to enumerate.

"As for operating from a distance torpedoes or submarines or dirigibles, which without crew or pilot should execute a work of destruction, that also would be possible. So far it has not been done in this war. It is obvious that an unexpected electric spark of atmospheric origin or coming from the enemy's side might provoke the action at a most inopportune time and in a most undesirable manner.

"In the field radiotelegraphy has proved itself most serviceable, as all know. The Germans make ample use of it. Their headquarters is thus united to Antwerp, to Brussels and to Lille. Radiotelegraphy was of great service to the 11 German warships which kept the sea for some months, doing a work of destruction. But it was also of service to the Allies for the discovery and destruction of those ships.

"As for the possibility of the enemy having on our territory hidden stations for radiomechanics, from which at a given time damage might be done, I doubt the utility of such a project. It would be easy enough to hide the antennae, but it would be impossible to hide the machinery," he intimated.

COLLEGE RADIO SET.

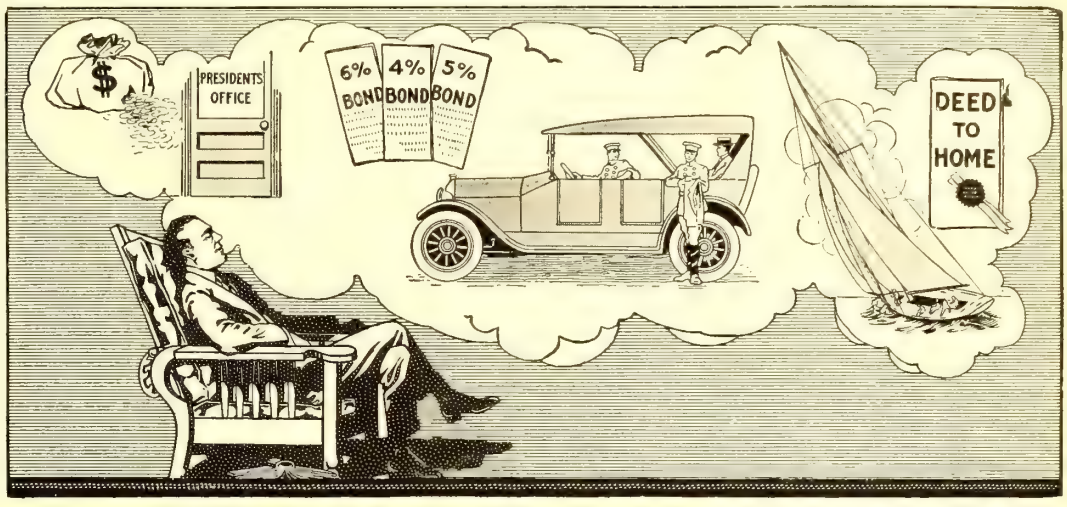
Prof. H. E. Robbins is at work on plans for installing a wireless telegraph station at the Agricultural College at Amherst, Mass. He has secured a 10,000-volt, three-quarter kilowatt transformer, crystal detector and head phones, and has applied for a room over the sophomore physics laboratory for the [illegible]. He proposes to

THE ELECTRIC ARC AND ITS INTERESTING APPLICATIONS.

(*Continued from page* 560.)

For the purposes of radio communication a smaller capacity and inductance should be used unless very high wave lengths are wanted. The inductance can be of the ordinary type oscilliation transformer, and variations in same can be made by means of clips.

Besides the uses enumerated above the arc has the very interesting property of being one of the chief factors requisite to the measurement of inductance and capacity, and is so used at the Bureau of Standards laboratories and elsewhere.



If at all possible for the experimenter to obtain the use of *direct current* it will certainly pay him to carry on investigations with this type of arc, as it will prove very interesting and instructive, and surely there is a large field for new discoveries.

Caution: When experimenting with the electric arc the eyes must be protected invariably by wearing "black" eyeglasses, procurable from any optician.

POPE TO BLESS WIRELESS.

The Exchange Telegraph Co.'s Rome correspondent says:

"Vatican circles announce that the Pope is preparing to bless wireless telegraphy officially, thus restoring the ancient custom of the Church to bless inventions which confer great benefits on humanity."

Partial Contents

The Law of Great Thinking.
The Four Factors on which it depends.
How to develop analytical power.
How to think "all around" any subject.
How to throw the mind into deliberate, controlled, productive thinking.
Detailed directions for Perfect Mind Concentration.
How to acquire the power of Consecutive Thinking, Reasoning, Analysis.
How to acquire the skill of Creative Writing.
How to guard against errors in Thought.
How to drive from the mind all unwelcome thoughts.
How to follow any line of thought with keen, concentrated Power.
How to develop Reasoning Power.
How to handle the mind in Creative Thinking.
The Secret of Building Mind Power.
How the Will is made to act.
How to test your Will.
How a Strong Will is Master of Body.
What creates Human Power.
The Six Principles of Will Training.
Definite Methods for developing Will.
The NINETY-NINE METHODS for using Will-Power in the Conduct of Life.
Seven Principles of drill in Mental, Physical, Personal Power.
FIFTY-ONE MAXIMS for Applied Power of Perception, Memory, Imagination, Self-Analysis, Control.
How to develop a strong, keen gaze.
How to concentrate the eye upon what is before you—object, person, printed page, work.
How to become aware of Nerve Action.
How to keep the body well-poised.
How to open the Mind and Body for reception of incoming Power.
This is only a partial list —a complete list of contents will be sent you.

Power of Will Makes Dreams Come True

Send No Money—Examine Book Free

Will Power, properly cultivated and directed, is the driving force behind your brain that turns empty air castles into happy realities. No man since the world began has ever achieved anything worth while without an inflexible will.

What do you want most in life? Money and all that goes with it? Reputation, Prestige, Power? Greater mental and spiritual happiness? Better self-control? More confidence in yourself? Whatever you want—whatever you have dreamed about some day having—can be yours, if you will only train your will as thousands of others have done with unfailing result.

Your Will Needs Practice

If you should stop work for two years and have no occasion to use your brain in solving business problems, you would gradually become unable to use it as you do now, simply from lack of practice. It's continual practice that makes it possible for you to arrive at quick decision and enables you to see the solution of vexing problems quickly. And you'd be surprised how soon the gift would leave you were you to get out of the harness for a few years.

The same is true of the Will. Because we don't use it, we don't know how. Most of us float along carrying out other people's wills simply because our own will has become scotched and dormant from lack of use. Yet the Will is just as susceptible to training as the brain or memory and by the very same methods, by intelligent exercise and use.

"Power of Will"

by Frank Channing Haddock, Ph. D., a scientist whose name ranks with such leaders of thought as James, Bergson and Royce—is the first thorough course in Will training ever conceived. It is based on a most profound analysis of the Will in human beings. Yet every step in the 28 fascinating lessons is written so simply that anyone can understand them and apply the principles, methods and rules set down with noticeable results almost from the very start.

400 pp. Half Leather Gold Top Leaves

May Transform Your Life

The users of "Power of Will" have experienced results through its study which border on the miraculous—it has enabled thousands to win out with big plans which they had worked on unsuccessfully for years—it has made active men of affairs out of pitiable down and outs—it has transformed those who had always been the pawn of others into self-confident powerful leaders—it has enabled men and women held down by petty fears—by trivial daily incidents—to brush them aside as though made of papier-maché—it teaches self-mastery—control of appetites and desires and it has enabled strong, successful men by the thousand to accomplish *bigger things* by giving them even greater power to use in their dealings with others.

No matter what your occupation in life—no matter what your age—"Power of Will" can help you by giving you the power to become the dominant factor in your every undertaking—by enabling you to make those with whom you come in contact work for your ends, instead of your fitting in with their plans, and what is equally important, it teaches you to so control your own actions that you can accomplish whatever you set out to do in spite of all obstacles. It invariably makes dreams come true—as over 75,000 men and women owners of "Power of Will" can tell you.

Send No Money—Examine Book First

Although "Power of Will" is a 400-page, leather-bound book containing more material than many $25 correspondence courses, the price is only $3.00. The publishers will gladly send a copy free, for five days' inspection. Send no money now. [illegible]

Over 75,000 Users

"Power of Will" has already helped over 75,000 people—a record equalled by no other single course of any kind in the world. Such men as Judge Ben B. Lindsey; Supreme Court Justice Parker; Wu Ting Fang, ex-U. S. Chinese Ambassador; Lieut.-Gov. McKelvie, of Nebraska; General Manager Christeson of Wells-Fargo Express Co.; Ernest Knaebel, Asst. Atty.-Gen. of the U. S.; Asst. Postmaster-General Britt; E. St. Elmo Lewis, now Vice-Pres. Art Metal Construction Co., are owners and literally thousands of other successful men like them have voiced their praise of this great work.

"From what I have already seen I believe I can get $300 to $30,000 worth of good out of it."—C. D. Van Vechten, General Agent, No. West Life Ins. Co., Cedar Rapids, Ia.

"'Will Power' is a compilation of mighty force. My first week's benefit in dollars is $900—cost $3; profit $897."—J. W. Heistand, 916 Tribune Bldg., Chicago, Ill.

"Send 15 copies to our New York office."—W. M. Taylor, Efficiency Expert, the Overland Auto Co., Toledo.

"He who reads it and puts forth effort will soon find himself out of the common herd."—F. A. Good, President of Nebraska Lumber Dealers' Assn., Cowles, Neb.

"Here is $3 for you. 'Power of Will' received. It is the book I've wished for for years."—J. L. Seawall, Clerk of Supreme Court, State of N. Carolina, Raleigh, N. C.

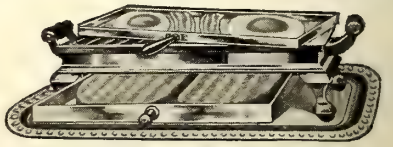
UNIQUE A. C. BELL TRANSFORMER.

A newly developed alternating current bell-ringing transformer of the step-down type has been brought out by a progressive electrical manufacturer. As the illustration indicates, the transformer is mounted directly back of the bell on the cover of any standard conduit box, such as those used in wiring houses for electric lights, etc. This makes a very neat and compact job and does away with the use of batteries, of course. The bell is of the ordinary vibrating pattern adaptable to such transformer current or to operation on battery current in the usual manner.



New A. C. Bell Transformer Mounted on Bell Itself.

HEAT CONDUCTION IN SELENIUM.

The fact that selenium changes its electrical conductivity so markedly with illumination has no doubt led many investigators to consider the possibility of a change in its heat conductivity with a change in the illumination. Bellati and Lussana, experimenting with a thin disk of light-sensitive selenium, found such a change and also noted that the percentage change in the thermal conductivity agreed well with the percentage change in the electrical conductivity where exposure was made to the same light. L. P. Sieg, in the *Physical Review,* mentions experimenting on a selenium crystal, and found that while the given source of light increased the electrical conductivity nearly 300 per cent., the same light did not increase the thermal conductivity in any appreciable manner; considering all possible sources of error, it must certainly have been under five per cent.

UNIQUE ELECTRIC STOVE.

A very neat electric stove has recently been brought out by a Western manufacturer, as a glance at the illustration will confirm. It combines four functions in one; in other words, it can be used as a toaster, a griddle, a broiler and a stove. The manufacturers guarantee it for five years. It comes complete with drip pan or tray, and also with a toasting pan, which slides in under the heating grids, besides a frying

Electric Stove of Many Uses.

BOOK REVIEW

WIRELESS TELEGRAPHY. By Dr. J. Zenneck. Translated from the German by A. E. Seelig, E.E. 443 pages; 469 illustrations; 6½x9½ inches. Cloth bound. Price, $4.00. 1915. McGraw-Hill Book Co., New York.

The latest acquisition to technical radio literature is here offered in this volume by Dr. Zenneck, the well-known wireless scientist. Much new matter is given in very attractive form of value to the general and advanced reader. A large number of important topics are covered mathematically and otherwise in an interesting manner. Some novel ideas are brought out on wave phenomena and particularly their propagation over the earth. The shape of the wave as it passes along the surface of the globe and the probable manner of overcoming such obstacles as hills, etc., is quite exhaustively treated upon. The author is an able authority on this subject and the reader will learn much by a perusal of this section as well as the very illuminating and lucid chapters on the natural oscillations of condenser circuits; open oscillators; coupled circuits; resonance curves; the antenna; undamped oscillations by the arc method; detectors; receiving circuits and their design; directive radio-telegraphy, etc., etc.

It is practically impossible to cover all the necessary laws and data on such a rapidly growing subject in a single volume, but this work is highly commendable in every way and should be read by all radio men. It seems as though the sections on arc type radio frequency generators, detectors, and high frequency alternators might have been advantageously extended. Some empirical deductions are cited in the chapter on "directive telegraphy" concerning the Marconi inverted "L" type antenna which seems somewhat far-fetched, in view of the fact that these antennae are in actual use by the Marconi Co., for long distance radio transmission over the Atlantic and Pacific oceans.

CHEMIST'S HANDBOOK. Issued by The International Correspondence Schools. Cloth covers; 5½x4¾ inches; 332 pages; 5 illustrations. Published by International Textbook Co., Scranton, Pa. Price, 50 cents.

The astounding part of this volume is the enormous amount of analytical data contained within its covers. It covers chemistry in a brief form and the tables are of use to every chemist, metallurgist or assayer.

The forepart of the book covers fundamental laws, atomic weights, chemical calculations and heat measurement. Analysis is handled in a masterful way with chapters on wet and dry analysis, assaying and blowpiping. The tables of results with different reagents are very valuable and blowpiping is covered in a manner that will be of assistance to anyone interested in this method of analysis and the tables of characteristic reaction cover 31 pages.

For the power plant engineer the subject of coal, boiler water and flue gas analysis is covered in a simple manner that assures the rapid and accurate calculation of the efficiency of steam plants.

TELEPHONE AND TELEGRAPH ENGINEER'S HANDBOOK. Issued by The International Correspondence Schools. Cloth covers; 5½x4¾ inches; 398 pages; 95 illustrations. Published by International Textbook Co., Scranton, Pa. Price, 50 cents.

A compact, reliable treatise on telephone and telegraph practise, the work of specialists in their line, and intended as a reference book for the practical man, aptly describes this little volume.

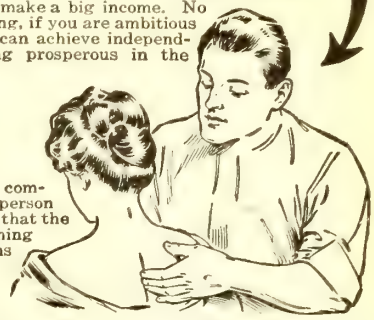
The aim of this treatise is to select, classify and place in the hands of the "man on the job" information and data that will be of practical assistance to him in his daily work.

The book starts with a brief treatment of mathematics, including various handy tables. Electrochemistry and mechanics are treated of so far as they bear any relation to the work of linemen, trouble-shooters or foremen. Wire tables and formula are given and the circuits in use are treated at length. The diagrams illustrating the latter are exceedingly clear and in many cases are full page drawings.

The latter part of the volume covers telegraph practise in a manner that will interest any telegraphist. A short treatise of wireless telegraphy is given, but this subject is rather briefly treated, only the general principles being given.

The book really gives a brief outline of the correspondence course on the subject by the I. C. S., but the volume will be invaluable to those in the least way interested in telephony or telegraphy.

GIRL BECOMES ENGINEER.



The power station at Studley College, England, is in charge of a 20-year-old girl. It includes a gas engine, dynamos and storage battery.

Become a Doctor of Chiropractic

Learn at Home—Earn $3000 to $5000 a Year

Here is your opportunity to qualify at home in your spare time to become a Doctor of **Chiropractic**—to enter an uncrowded profession and make a big income. No matter where you live or what work you are now doing, if you are ambitious our Course in **Chiropractic** shows you how easy you can achieve independence. Men and women everywhere are becoming prosperous in the practice of this fascinating profession of

DRUGLESS HEALING

Never before has the demand been so great for competent Doctors of **Chiropractic.** Every thinking person knows that the day of Drugless Healing is here, and that the masses of people everywhere are eagerly welcoming **Chiropractic,** the science of restoring health by means of spinal adjustment, as a natural, scientific substitute for the old outgrown system of "dosing" by internal medicines.

5 Lessons Free to Convince You

Make Money Practicing Chiropractic, the Science of Spinal Adjustment

To show you quickly and convincingly what **Chiropractic** is, we offer you 5 Lessons of our Regular Course absolutely **Free**—also our Big 64-Page Book and Eight (8) Anatomical Charts beautifully lithographed in lifelike colors that regularly sell for $15.

You can become a **Doctor of Chiropractic** in a surprisingly short time by our practical, easy simplified method of home instruction. All needless theory is thrown aside—our course offers the shortest, most direct route to your degree of D. C.—Doctor of Chiropractic. **We give you,** right in your own home during your spare time, just the training **you must have to succeed.**

WE WANT YOU TO

ACCEPT THIS BOOK FREE

IT'S INVALUABLE YET CAN'T BE BOUGHT

Just as you will receive it, cloth bound, size 7 x 10¼ ins., 160 pages, 20 lessons, 350 illus., 30 tables, with every bit of information on Wireless you can possibly want, besides valuable information on Electricity, Magnetism and Theory of them **—and it's FREE as explained.**

Will you take a 20 lesson Wireless Course absolutely FREE—even postage charge prepaid ?

A course that tells you everything you can possibly want to know about "Wireless" starting off in Lesson No. 1 by explaining the Principles of Electricity. The Second and Third Lessons are devoted to magnetism, motors; generators and wiring. And then, by simple easy stages this wonderful Course takes you into "Wireless." The mysteries of "Wireless" are unfolded to you by the use of such simple language so skillfully used, that of necessity you must understand every word. The subject is not treated superficially, however, for there is a whole lesson devoted to the Theory and Mathematics of this epoch marking subject. To lend charm to the Course, the last Lesson (No. 20) is devoted to a history of Wireless and the men who developed it. The wireless course positively cannot be bought, but will be sent absolutely free with a full year's subscription (12 numbers) of the Electrical Experimenter at $1.00. It's the biggest dollar's worth you can ever buy anywhere at any time. Send for it to-day enclosing $1.00. Send **now** before you forget.

The coupon below is a convenient way. **But do it now.**

Just Off The Press

TWO REMARKABLE BOOKS

100 PAGES, 88 ILLUSTRATIONS

How to Make Wireless Sending Apparatus

THIS book will surely be welcomed by every wireless enthusiast and by everyone who is fond of making his own apparatus.

This book contains more information on how-to-make up-to-date sending apparatus than any other book we know of. Thirty different pieces of apparatus can be made with materials that most anyone can obtain without much trouble; the illustrations and descriptions being so clear and simple that no trouble will be experienced in making the instruments. Only strictly modern and up-to-date apparatus are described in this book and if we asked you 50 cents for it we are sure that you would consider it a bargain.

This book has been written by twenty radio experts who know how to make wireless sending apparatus and for that reason you will gain by their experience as well as by their experiments.

The size of the book is 7x5 inches substantially bound in paper; the cover being printed in two colors. Contains 100 pages and 88 illustrations. There are quite a few full page illustrations giving all dimensions, working diagrams as well as many photographs showing the finished apparatus.

PRICE 25c. PREPAID

100 PAGES, 90 ILLUSTRATIONS

How to Make Wireless Receiving Apparatus

WE know that this book will surely be a boon to every "How-to-make-it" fiend. It has been written and published entirely for the wireless enthusiast who makes his own receiving apparatus; the twenty radio constructors who have written the articles are well-seasoned in the art and know whereof they speak. You consequently profit by their experience.

Only strictly up-to-date and modern apparatus are described and only those that the average experimenter can make himself with material that can be readily obtained.

We believe that *this book contains more information on how to make wireless receiving apparatus than any other book in print* and you will find that it is easily worth double the price we are asking for it.

The size of the book is 7x5 inches, handsomely bound in paper; the cover being printed in two colors. Contains 100 pages and 90 illustrations. There are a number of full page illustrations giving all dimensions, as well as photographs showing finished apparatus.

PRICE 25c. PREPAID

Send for these two books today.

Scientific Exchange Columns

UNDOUBTEDLY you have at the present time some things for which you have no further use. Do you wish to exchange them for something, for which you have immediate use? There is no surer and quicker way to do this than by advertising your articles in these columns. The **Very** people, the **Only** people, who could possibly have a use for your things read this journal. More than 40,000 interested people will see your ad. It is furthermore the cheapest advertising medium for you in the country. Dealers' advertising accepted in Opportunity Exchange Columns only.

The rates are: One cent per word (name and address to be counted) minimum space 3 lines. Count about 7 words to the line. **Remittance must accompany all orders.** No advertisement for less than 10c. accepted.

We reserve to ourselves the right to refuse any advertisement **which we** consider misleading or objectionable. Advertisements for the March issue should reach us not later than February 5th.

The Classified Columns of "The Electrical Experimenter" Bring Positive Results.

Subscribers experiencing trouble in dealing with any advertiser should notify the publisher very promptly.

DeFOREST audion detector, type R J 5 (with new batteries and X grade Hudson filament bulb), $16; cost $29. J. S. McDonnell, 3304 Eighth Ave., Little Rock, Ark.

COMPLETE wireless outfit, worth $87.95, and slide trombone, "Frank Holton Special," worth $62 with case; would sell wireless outfit for $40, trombone $30; or exchange all the above for high-powered high-frequency apparatus. Send for particulars. East Germain, Ashland, Mass.

WILL TRADE $20 A. C. S. course in mechanical and architectural drawing (four volumes, like new), for wireless receiving instruments. All letters answered. Harold Shirley, Lebanon, Ind.

EXCHANGE D. C. motor for type A.A. Crystaloi; Motsinger magneto for adjustable tubular sending condenser. E. I. make. Albert Heyman, 227 S. 20th Ave., Minneapolis, Minn.

HAVE a 1½ K. W. transformer. Want rotary gap, audion or loose coupler. No home-made apparatus. Harold Craven, Selma, Cal.

FOR SALE—Electro $7.50 loose coupler, $4; Electro ½ K. W. transformer and interrupter, $5. Instruments in excellent condition. No parts broken. Stuart W. Pierson, Carrollton, Ill.

PERSONAL INSTRUCTIONS in chemistry by expert chemist, 50c. per lesson. Will exchange for wireless or electrical apparatus. Enclose stamp. Elbridge F. Ball, Buckland, Conn.

WILL EXCHANGE commercial job printing for good or burnt-out audion, audion amplifier bulbs, variable condensers, Crystaloi, or offers. Enclose stamp. E. Ball, Buckland, Conn.

FOR SALE—One 4 H. P. Pope motorcycle engine set in iron frame with extra flywheel. Can be used for stationary work, including spark coil—all in good condition. The first ten dollars takes it. All letters positively answered. Emil Roth, Castle Shannon, P. O., Pa.

NOTICE! We buy, sell and exchange wireless instruments. Have many real bargains and have demand for used instruments. Tucker & Dewey, Box 755, Hartford, Conn.

WILL PAY CASH for audion bulb. Must be in good condition. J. Wallace Peckham, Melville, Newport, R. I.

EXCHANGE—Have .32 revolver, Murdock loading coil, Murdock condenser. Want A.A. type Crystaloi detector. Bernard Bisciotti, 608 Carpenter St., Philadelphia, Pa.

HAVE high-grade 1½ K. W. sending and receiving wireless sets, everything complete and in A No. 1 condition, which I wish to exchange for refracting astronomical telescope, must be high-grade instrument, or Harley-Davidson motorcycle side-car. Dr. Mack, 256 Fifth Ave., Pittsburgh, Pa.

SWITCHES FOR SALE—"Electro" aerial switch (new), price $1.35; "Electro" 100-ampere lightning switch (new), $1.25, both for $2.50; porcelain base knife switches, double pole, double throw, each 25c.; double pole, single throw, each 16c.; wood base switches (1 point), 6c. each. Write quick. Louis Menier, 443 E. 85th St., New York City.

FOR SALE—One "Electro" dynamo, type "SS" (new), price $3.20, and one "Electro" 4-inch water motor (new), for $1.85. Both for $4.80, including Universal coupling for water motor. Write quick. Louis Menier, 443 E. 85th St., New York City.

FOR SALE—The first remittance for $2.75 takes a pair of E. I. Co. 2,000-ohm Jr. wireless phones No. 8090, in excellent condition. Beall Taylor, Rivermont Ave., Lynchburg, Va.

FOR SALE—Slightly used Amco humming transformer, $6.75; 1 K. W. helix, $2.50; new $7 Chambers receiving transformer, $5.50; also $12 electric train and track, $4. Want Blitzen $4 and Murdock $3 variables. Will pay cash. Harry McCarthy, Huntingdon, Pa.

FOR SALE—"Climax" concrete brick machine, makes plain and fancy bricks, $6.50; concrete column moulds, rock and panel face, 8, 12, 16 inches, $2.75 to $3.50; round column mould, $3. All in good condition. Sand screen, $1. Lloyd Gress, Pitman, N. J.

WANTED—Constant speed spring motor that will run at least 30 minutes, power stronger than phonograph motor. Also unused audion bulb. Fair prices will be paid for these articles if in good condition. Wm. H. Trippe, Toms River, N. J.

WANTED—Crystaloi resonator; Crystaloi or Perikon detector; variable condenser; 3,000-ohm headset; aerial switch; Electrose insulators; oscillation transformer. Eugene C. Braatz, Lowellville, O.

HAVE large-size static machine for X-ray work, large-size tube and insulated stand. Would like for it a 1 K. W. hytone set or ½ K. W. hytone and audion. Anyone having Blitzen transmitter please make offer. Clayton B. Shelby, Barker, N. Y.

$3.10 giant sounder, 75-ohm phone, 27 wireless magazines, ounce copper pyrite. Want phones or sale. Karl Dueck, Defiance, O.

FOR EXCHANGE—"Caligraph" typewriter, 20-ohm sounder and key, audible telegraph transmitter and reels, three 6-volt 9-candlepower "Mazda" bulbs and sockets. Want headset, loading coil, fixed and variable condensers, potentiometer. J. Walter Briggs, Stanfordville, N. Y.

WIRELESS receiving set, consisting of single-slide tuner, new silicon detector, condenser and 1,000-ohm phone, $5. Elmer Baier, 444 Seventh Ave., Brooklyn, N. Y.

FOR SALE—Audion detector, similar to R J 5 but mounted on top of cabinet; cost $30 and is almost new, but needs new high-voltage batteries. Will sell for $15 (express paid). Act quick. I guarantee audion to be in first-class condition. Peter A. Stover, Marengo, Ia., Box 106.

FOR SALE—Amco $7 oscillation transformer, $4. Never been used. Murdock 2,000-ohm headset, $2.50. Write. Arnold Rufsvold, 3216 16th Ave. S., Minneapolis, Minn.

EXCHANGE — Clark Irish harp, ohm-meter, thermo-pile, galvanometer, auto lighting generator, gas headlights, garage power air compressor with tank. Want engine lathe, prism binoculars, tiger rug, or what have you, excepting books, wireless apparatus, stock or real estate? Joseph Lamb, 563 Baldwin Ave., Detroit, Mich. All stamped letters answered.

HAVE electrical course complete; also Seneca folding camera. Want chemistry books, microscope, telescope and drawing instruments. Roy Heath, Highland Park Station, Des Moines, Ia.

WILL EXCHANGE complete receiving set for Knapp type "SS" dynamo motor. Write for descriptive description and lists. Will pay cash for Brandes transatlantic phones. Will answer all letters. David Goodman, 418 W. Court St., Flint, Mich.

FOR SALE—One No. 5 "Structo" and $5 worth of extra parts, cost $15 new; will sell for $8. One Gem adding machine, cost $10 new; will sell for $6. One Remington typewriter, cost $100 new; will sell for $35. Frederic Peterson, 811 Washington Ave., Red Oak, Ia.

FOR EXCHANGE—One A. C. arc lamp, 60-120 cycle, cost new $35, for battery-charging generator and automatic cut-out. H. B. Rice, Galeton, Pa.

WANTED—A copy of bound Vol. No. 1 and No. 2 of The Electrical Experimenter. Write A. B. Chance, Centralia, Mo., stating price.

FOR SALE—¼-kilowatt transformer and condenser in oak cases. Winger transformer gives 14,000 volts. First reasonable offer accepted. Bayard Shumate, Lebanon, Ind.

FOR SALE—Electrolytic detector, 85c., and E. I. Co. potentiometer, 95c.; both for $1.75. Rosswell Brown, 748 E. State St., Huntington, Ind.

FOR SALE—Transmitting set, including Packard transformer, Sayville rotary gap, two sections Murdock condenser, Clapp Eastham antenna switch, Murdock oscillation transformer and Bunnell key. Will sell for $25, or trade for R J 5 audion in good condition. Carlisle Benjamin, Clyde, N. Y.

ELECTRICAL LIBRARY, I. C. S., nine volumes, $15; head receivers, $2. O. M. Jones, Des Moines, Ia. No. 45 H. P. Sta.

HAVE brand new Nichols sending and receiving wireless station No. 402. Cost $7.25; will sell for $3.25. Carl Barany, 245 W. 35th St., New York City.

A 220-volt 1-12 H. P. enclosed D. C. motor. Want Brandes, navy or transatlantic phones or cash. Henrik Juve, Enterprise, Ore.

FOR SALE—1 K. W. Thordarson transformer, Murdock oscillation transformer, complete unmounted rotary gap (motor 7,000 rev. per minute A. C.), oil immersed condenser. Will sell to first reasonable offer; all answered. Henry Messerly, Staunton, Ill.

FOR SALE—Electro amateur phones, $3; Gernsback variable condenser, $3; Electro loose coupler, $3; electrolytic detector, $1; potentiometer, $1; motor, 50c.; telegraph set, 75c. Harry Holmberg, Bottineau, N. D.

WANTED—Tesla coil X-ray apparatus, ½ kilowatt flexible transformer, 2-inch coil, audion bulbs, burnt-out or good, and heavy key. Every letter answered. Will pay cash. Harry Smejkal, 1349 First Ave., New York City.

FOR SALE—½-inch spark coil, $1.50; spark gap, 35c.; Amco key, 50c.; Radio Apparatus Co.'s key, 35c.; Amco "Little Giant" motor, 35c.; flashlight, 40c. Write to Louis Enslin, No. 21 Street, Philadelphia, Pa.

BARGAIN—Edison standard $40 phonograph, good as new; 150 records; price, $50. Write for particulars. J. L. Dunnell, Northfield, Mass.

WANTED—Back numbers of aeronautical magazines; also The Electrical Experimenter, Vol. 1. What have you? L. Koerner, 312 W. St. Vrain St., Colorado Springs, Col.

FOR EXCHANGE—Stamp collection in Scott's Best Album Cat., over $35. Want printing press, camera or electrical apparatus. Oscar E. Noreen, R4, Gresham, Ore.

FOR SALE—Two telegraph sounders, 50c. each; one electric car and outfit, cost $3, will sell for $1.50; two motors, 50c. each; telephone transmitter, 50c. H. Moersbfelder, 34 Ketchum Pl., Buffalo, N. Y.

MOTION PICTURE FILMS, $1 reel up. Chas. Chaplin, etc. Will trade. If you mean business, write. Enclose stamp. Kenneth Woodward, 24 Lenox St., Uniontown, Pa.

FOR EXCHANGE—I have a complete ½ kilowatt sending set and an audion receiving set, complete, with necessary switches, aerial wire, insulators and two storage batteries; also lots of other electrical apparatus; complete value, one hundred and fifty dollars. Want a motorcycle, or will sell or exchange separately. What have you? Allan Lawson, 108 Walnut St., Waterbury, Conn.

WANTED—Any electrical or gas engines bought; good price. Kenneth Lee, Purcell, Okla.

HAVE 6-volt, 8-ampere D. C. Remy magneto in good condition; cost $10. Can be used as motor. Want good coil, 2 or 1½-inch, depending on make and condition. Kenneth Bard, Manawa, Wis.

WANTED—½ or ¼ K. W. transformer, audion bulb, good or broken, and spark gap. Will trade articles or pay cash. Would like to exchange photographs of stations. Alexander Bollerer, 77 Linwood St., New Britain, Conn.

FOR SALE—A Packard ½ K. W. transformer in oaken case, with power variations controlled by switch, and condenser for the same. Price, both together, $9. Wm. Bride, 116 E. Haverhill St., Lawrence, Mass.

ONE radio 3,000-meter loose coupler, galena, two Universal electrolytic detectors, rotary potentiometer, two 43-plate variables, $10, cost $24. Claxton horn, Stewart speedometer, motorcycle electric lamp, $7, cost $20. Sold separately. Want 3,000 phones, audion detector or bulb, ½ K. W. closed-core sending instruments. H. Hawks, Fleming, Pa.

HAVE telegraph key sounder and about 50 feet of wire to exchange. What have you? M. R. Heslowitz, 151 Peshine Ave., Newark, N. J.

FOR SALE—Edison kinetoscope; also ¼ H. P., A. C. 110-volt electric motor, fluoroscope X-ray tube and centrifuge. H. S. Partee, Biddle University, Charlotte, N. C.

HAVE a motor bike engine, .22 Savage high-power rifle, piano player, single Merkel motorcycle, stereopticon and other articles to exchange for a 2 K. W. 110-volt generator, small lathe, electrical experimental articles. H. A. Margreiter, LaPlata, Mo.

MURDOCK APPARATUS—Loose coupler, $6; loading inductance, $2; detector with condenser in base, $1.50; Blitzen variable condensers, 43 plates, $3; 31 plates, $3.50; all equal to new. Sent P. P. C. O. D. Wm. Ranft, 4107 Belle Ave., Baltimore, Md.

FOR SALE—Type "S" dynamo motor, $1.50; in good condition. Letters answered. Ernest Becker, Isleta, O.

FOR SALE—Blitzen receiving cabinet set; hand bench punch, weight 130 lbs.; metal splitting shear, weight 100 lbs. Write for particulars. C. F. Lee, 1417 Belleplain Ave., Chicago, Ill.

"ARLINGTON" receiving set, only $6, mounted ready for use; gets Arlington loud with small aerial. Send for photo and description. A. Newman, 685 W. Ferry, Buffalo, N. Y.

FOR SALE OR TRADE—Books on adventure, etc. Clean, live and wholesome. Make me at least an offer. For particulars write Chas. Hrdlicka, Lesterville, S. D.

EXCHANGE—Meccano outfit No. 4, $6 motor, high-grade radiopticon and 4 H. P. motorcycle engine. Want wireless apparatus. E. W. Pennington, 3236 Stevens Ave., Minneapolis, Minn.

WANTED—A cabinet receiving set in exchange for moving picture machine, no toy. Have three violins, guitar and xylophone. What have you in the receiving line? Harold Buckner, Morgan Hill, Cal.

FOR SALE—Complete loose-coupled wireless receiving outfit, standard amateur type, including aerial, ground and connecting wire and accessories. Cost $12; will sell for $6. Write for description. H. Frankland, 517 W. 113th St., New York.

EXCHANGE—Set of five electrical books, two-point annunciator, wall telephone and other goods. J. Forsht, Box 861, Lock Haven, Pa.

EXCHANGE—Bass violin 6 feet tall, best condition, except strings, for wireless sending set. R. J. Morrison, Cherryville, N. C.

FOR SALE, Twenty dollars, or separately: Mignon coupler, three thousand ohm telephones, load, fixed and variable condensers, eight Electrose insulators, six mineral detectors, minerals and switches. Meeker, 511 W. 186th St., New York.

FOR SALE—One Eastman No. 3A Brownie and complete outfit in good condition, with developing tank. First money order for $10 takes it. Chester Ickes, Reynolds Dale, Pa.

BIPLANE GLIDER—Upper plane, 24x4½; lower, 20x4½; length 16 ft. New, worth about $60. Will exchange for wireless goods, cyclecar, motorcycle or motor. H. W. Craver, 222 Custer Ave., Youngstown, O.

WANTED—Burnt-out audion bulb; will pay $1.50. Charles Bunker, 114 E. Carter Ave., Ashland, Ky.

FOR SALE cheap, in good condition: Loose coupler, potentiometer, electrolytic detector, single-pole, thousand-ohm receiver and cord. Write Wm. W. Macalpine, 5845 Phillips Ave., Pittsburgh, Pa.

WANTED—A pair of two or three thousand ohm phones and headband. Harry R. Fees, Guthrie, Okla.

FOR SALE—An engine and coal car 2 feet long, three cars measuring 15 inches each, 19 feet of 2¼-inch track, two switches; all cost $40. Will sell for $20. All in perfect condition; selling because interested in wireless. Holden Booth, 3529 Ainslie St., Philadelphia, Pa.

BARGAINS—Nar meter loose coupler, $3.50; American Model Builder No. 6, $7.50. Want ½ K. W. closed-core transformer, rotary gap. All letters answered by Carl Linxweiler, 140 Eagle St., Dayton, O.

TRADE—Type "SS" Knapp dynamo-motor and small medical coil; both in good condition. Want burnt-out audion globe and two sockets for same. Write Tom Sides, P. O. Box 375, Selma, Cal.

FOR EXCHANGE—Rhumkorff ¼-inch spark coil of mahogany woodwork, cost $6 when new, for a good audion bulb. Joseph Terleph, Brown Ave., Jamaica, L. I.

FOR SALE—One 2¾ H. P. Indian engine, $9; one 3 H. P. boiler and engine, including all gauges and governor, with sufficient new pipe fittings to install, $20. Will exchange one 2 H. P. 220-volt D. C. motor, less field coils, for typewriter. Send stamp for particulars. Gregory Fay, 1024 Bellevue Ave., Syracuse, N. Y.

FOR TRADE—Series telephone and telephone parts, magic lantern with five hundred views, musical instruments. Exchange for Omnigraph, tape register, or what have you? S. H. Rudy, R. F. D. No. 4, Fairmont, W. Va.

FOR SALE OR EXCHANGE—Complete wireless receiving or sending apparatus, worth $49.50, for $20 cash; or separate parts sold for one-third price. Send stamped envelope for reply. Write at once. Robert Roth, 2023 Evergreen Ave., Chicago, Ill.

SPECIAL NOTICE—Will sell my Electrical Engineering books, civil, chemical and two $10 medical books, magazines on electricity, such as Electroforce, for what you can offer. Write or send 50c. for samples. Robert Roth, 2023 Evergreen Ave., Chicago, Ill.

BARGAIN! Complete wireless outfit (new), cost $50; will sell for $30 if taken at once. Also have printing press for $2; catcher's mitt, with league, for $3. For particulars write Fred Roewekamp, 202 Wangoo St., Oshkosh, Wis.

FOR SALE—New 2-inch coil, $5.75; Brandes Superior phones, $4; gas postcard projector, cost $5, will sell for $2.50. H. Moershfelder, 34 Ketchum Pl., Buffalo, N. Y.

FOR SALE—12-inch fan, D. C., 1-6 H. P.; $4 takes it. Two-cylinder spark coil (French make), $5. Manuel Rattner & Bro., 36-38 Union St., Poughkeepsie, N. Y.

FOR SALE—½ K. W. induction coil with vibrator, $4.50; ½ K. W. helix, $2.50; and a receiving transformer, tunes up to 3,500 meters, $2.50; five cells Exide storage battery, $30. R. J. Freeman, Aloah Radio Sta., Southampton, N. Y.

FOR SALE—Electro transcontinental receiving set No. 1603, with 3,000-ohm phones, aerial wire, insulators, lead-in cable, wireless course, etc. Cost $33; never been used; $25 takes it. A. G. Afton, 521 Ash St., Osage, Ia.

FOR EXCHANGE—Lionel train, two reels of film, 180-ohm relay, Brownie camera, 110-volt motor and rheostat, ½ H. P. Would like any of the following: Audion, variable rotary condenser, headset. What have you? A. H. Dreesner, 89 Dorman St., New Haven, Conn.

FOR SALE—Rotary gap disc, $1.25; Electro wireless course book form, 50c.; Rex motor, 40c. Rudolph Wensko, 2146 W. 81st St., Cleveland, O.

LOOSE COUPLER—Tunes to 2,000 meters, woodwork solid oak, primary and secondary varied by switches, $6, express paid. Also a 1,000-meter loading coil, woodwork solid mahogany, $2.25, prepaid. W. H. Ritter, 2748 N. 22d St., Kansas City, Kan.

EXCHANGE—I. C. S. electric lighting course and first-class drawing outfit, complete. Want 2-inch spark coil, Tesla coil or other experimental or wireless goods. Edward Olson, R. No. 1, Mt. Vernon, Wash.

WOULD LIKE to exchange a 110-volt, three-speed direct-current General Electric fan, worth $15; a medical coil, $3.50; Knapp electric question board, $2.50; a $15 boy scout snare drum; $5 Erector building set. Would like wireless apparatus, or I prefer a large electric train and equipment. Arthur Vernier, 34 Beecher Ave., Detroit, Mich.

$6 takes inductive coupler in hard rubber cabinet, coupling and turns varied by knobs. Want two 43-plate variables. Francis Pray, 102 Heath St., Somerville, Mass.

SELL OR EXCHANGE—Thordarson step-down transformer, bargain, $3.25; Brandes 2,000-ohm phones, $3.50; loose coupler, 3,000 meters, $2; volt-ammeter, new, 90c.; Mesco beginner's outfit, 85c. Other wireless apparatus and electrical books for sale. E. Braatz, Lowellville, O.

FOR SALE at a bargain: Nichols Gem set, detector, single-slide coil, Electrose insulators, carbide lamp. Electro fixed variable condenser, transmitting wave-reducing condenser and four-strand antenium aerial wire; all practically new. Make me offers. John A. Irvin, Cannelton, Ind.

BARGAIN — Perfect four-miler, Bunnell one-inch coil, zinc gap, Gernsback interrupter, fuse block, Victor key, two-glass plate condenser, D. P. D. T. switch; all $5.50. Receiving 1,500 miles. Bornite and zincite detector, Bunnell 500-ohm receiver, three-slide tuner, two fixed condensers, three antenna insulators, switches and sundries; all $2.75. Money order or cash, either or both shipped. R. W. Howe, 1120 Amsterdam Ave., New York.

HAVE 8 H. P. gasoline engine complete, 4 H. P. Gray marine engine, complete, with salt water fittings, never uncrated or used, and other apparatus. Want audion, automatic pistol, transformer, camera, anything electrical or wireless, or cash. Make offers. Send stamp. Clyde P. DeLancey, Box 71, Hampton, N. H.

FOR SALE—Several numbers "Electrical Experimenter," "World's Advance," "Modern Mechanics," "Popular Electricity and Modern Mechanics," one Morgan's "Wireless Telegraph Construction for Amateurs" and three handbooks; all going cheap. H. Frankland, 517 W. 113th St., New York City.

Opportunity Exchange

YOU will probably find more opportunities and real bargains in these columns than anywhere else in the country. Most good things in life are hard to find and worth going after—these little ads illustrate that point; you alone will be the real loser if you don't take the time to scan through these columns.

Advertisements in this section 4c. a word for each insertion. Count 7 words per line.

Name and address must be included at the above rate. Cash should accompany all classified advertisements unless placed by an accredited advertising agency.

Ten per cent. discount for 6 issues, 20 per cent. discount for 12 issues from above rate. Objectionable or misleading advertisements not accepted.

Advertisements for the March issue should reach us not later than February 5th.

EXPERIMENTER PUBLISHING CO., INC., 233 Fulton Street, New York, N. Y.

BOOKS

WANTED—Cosmopolitan Magazine, August, 1900; also Current Literature Magazine, October, 1900. Box 110, Marrill, Neb.

OPERATORS—Just the thing when on a cruise. The Midget Bible, size of postage stamp; 250 pages and illustrations. Sample, 10c. Wonder Co., 416 E. 135th St., New York City.

WARNINGS

And Advice to Small Investors:

by Erardus Sagra, who tells how he avoids loss and succeeds in receiving large returns for the investment of comparatively small sums of money in honorable and safe enterprises. His valuable experience, for which he charges $1 (by money order or registered letter; no stamps accepted) will save you quite a little fortune if you have a little patience. Satisfaction guaranteed or money refunded. Erardus Sagra is also the author of "The Might of Truth," the price of which is $1 net; but temporarily it has been introduced at the nominal price of only 24c. This interesting book is FREE to all who order the above mentioned "Warnings and Advice to the Small Investor." Those who purchased this book already at the nominal price need not send more than 75c. (It will take from three to four days to fill your order.) Address M. T. Dept., Box 2034, Middle City Station, Philadelphia, Pa.

HAVE you seen a copy? Amateur Photographers' Weekly, $1 per year; weekly prize competitions; criticisms; print exchange; illustrated; many features. Three months' subscription, 25c. Amateur Photographers' Weekly, 915 Schofield Bldg., Cleveland, O.

MISCELLANEOUS

THE AMCO NAVY TYPE RECEIVING TRANSFORMER

Represents the latest advances made towards the ideal tuner and embodies the greatest degree of perfection yet obtained. No greater value can be secured where accurate selectivity, sensitiveness and finish are desirable. The illustration shown herewith cannot possibly do justice to the instrument itself. The primary winding is enclosed in a cabinet, the sides and top of which are polished hard rubber. Two 15-point switches are mounted on the front. One switch controls the primary in groups of several turns and the other controls one turn at a time. The entire variation of the primary is thus secured by the rotary motion of two knurled knobs rather than the movement of a slider, and may be varied from 1 to 225 turns in steps of one turn at a time. The windings are especially adapted to long wave lengths. The secondary is wound with green silk covered wire. The ends are HARD RUBBER, turned and polished. Secondary variation is secured by a 12-point switch which makes it possible to secure a very fine adjustment. **PRICE, ONLY $15.00**

You Can Now Learn at Home To Be An ELECTRICIAN

This is the age of Electrical Miracles! Electricity rules supreme as the motive power of the world. Its wonders are growing every day, on every side of us, in every aspect of modern life and industry. It is **opportunity!** And still, as **Thos. Edison** says, the field of Electricity is only in its infancy. The student of Electricity today will startle us with new marvels tomorrow. Right **now** we need men who know Electricity. There are not enough electrical workers to fill the big paying positions open. Every day the call for men grows more insistent. Feeling the pressure of this demand we are now making a remarkable special offer to students at this time.

EARN $2,500 TO $4,000 A YEAR

I Will Teach You Personally By Mail

I will give you my personal and individual attention. Makes no difference who you are, where you live or what you do, I will train you by mail to become an Expert Electrician capable of earning $2,500 to $4,000 a year. My instruction is based on my own extensive, practical, everyday experience. I know just the kind of training you need for the big money job. No needless theory—no drudgery. You don't have to take a minute from your regular work.

Don't think you have to have some electrical experience or knowledge to take advantage of this opportunity. Under **my new** system of instruction you don't!

You will marvel at the progress you will make under my instruction. Each lesson makes you more eager for the next. And in an astonishingly short time you have mastered the entire course and become an Expert Electrician! The cost to you just now is so small as to be insignificant. You can pay the small tuition fee in payments so easy that you'll scarcely miss the money.

20 Complete Lessons FREE!

Never before has an offer so liberal been made on a Course in Electricity—probably will never be made again. I make it now because at the present time there is an **unusual** demand for trained Electricians and it is to my advantage to offer **exceptional inducements** to prospective students. I want to make it so easy for ambitious men that no possible excuse can be had for not accepting my wonderfully liberal offer. But the Free Lesson offer is limited, good for only 23 days. And there are only a limited number of these lessons to be given away free. So **send the coupon at once.** Let the free lessons prove how easy it is to become an Expert Electrician by my methods.

Send No Money—Just This Coupon!

Write today for full description of course and particulars of our amazing offer of 20 lessons Free. Even if you had not planned to enter the Electrical field don't fail to get all facts of this remarkable opportunity. Send coupon or postcard. No obligations on your part. Act at once—while this offer is open.

TWO PIECES OF METAL TONED ALIKE

"Superior" Set. Price $5.00 complete, including headband

will both vibrate when one of them is struck. This same principle has been applied to Brandes Wireless Receivers. By perfectly matching the tone of the two receivers, the weak sounds that you would otherwise lose, are brought out so as to be easily interpreted.

Brandes Wireless Receivers are made expressly for wireless service; they are not telephone receivers adapted to serve the purpose.

They are very light and easily adjustable. No pinching or slipping. You set them to fit exactly; after that they're as easy on your head as your hat.

Our Catalog E contains some very valuable information about radio receivers, as well as a full explanation of several types of Brandes head sets. Send 4c. in stamps for your copy to-day.

DUCK'S NEW BIG No. 9 320-PAGE ELECTRICAL and WIRELESS CATALOG

MORE THAN EVER JUSTIFIES YOUR VERDICT THAT IT IS THE *ONE* CATALOG WORTH WHILE

15,000 of our catalogs ready for delivery to eager electrical and wireless enthusiasts in all parts of the world. One of ten consecutive shipments of catalogs to our patrons during last November.

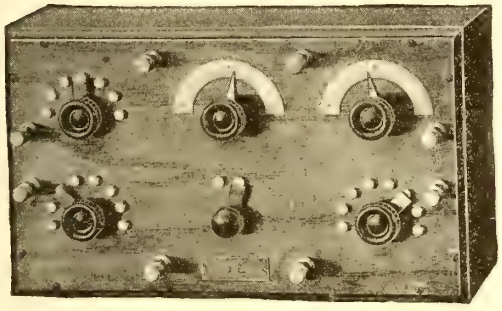
150 pp. Wireless Instruments.

170 pp. Electrical Supplies.

Over 40 pp. of Wireless Instruments.

Only 8c. in stamps will bring this unrivalled catalog to your home. The great cost of catalog and the exceptionally low prices (oftentimes fully 25% below usual retail price) prohibits its distribution otherwise. You may deduct the 8c. on first $1.00 purchase.

WHAT OUR BIG CATALOG CONTAINS



150 pp. Wireless Instruments, magnet wire of all kinds, raw material, storage batteries, telegraph instruments, battery motors, commercial motors and generators, sewing machine motors, telephones, step-down transformers, massage vibrators, bells, push buttons, auto accessories, flash lights, hand lanterns, auto and miniature lamps, Xmas tree outfits, voltmeters, ammeters, lighting plants, Victrolas, air rifles, electric aeroplanes, model builders, electric railways, electrical and mechanical books and general electrical supplies.

The William B. Duck Co., 230-232 SUPERIOR ST. TOLEDO, OHIO

NEW VARIOMETER

A De Luxe Wireless Receiving Station

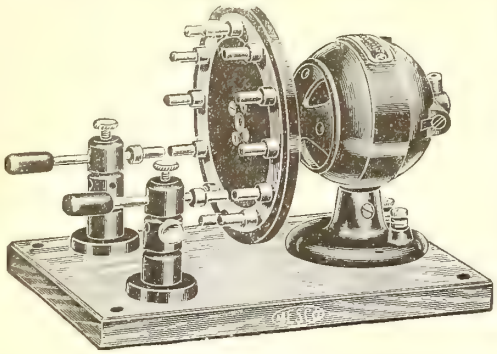
Wave Length 3,000 Meters On An Average Length Antenna

DE LUXE improved variometer a complete Station to receive N. A. A. Arlington, Va., N. A. R. Key West, Fla., W. S. T. Miami, Florida, capable of receiving all government or commercial Stations along the coast, and has a wave length of 3,000 meters on an average antenna.

The Station consists of variometer tuner working on entirely new principles, different from any heretofore offered. It consists of a primary and secondary loading inductance placed in non-inductive relation to each other. The Tapped Loading Inductance does the tuning by means of units and tens switches, which produce the most efficient tuning.

A Short wave variable condenser is placed in across with the antenna so as to enable you to work the amateurs at leisure, another variable is placed across the secondary by means of which the capacity of the secondary circuit is raised to a higher wave length. In this set is placed a new Instant Radiograph in place of a detector which will enable you to receive signals instantly at all times without loss of time or messages.

This Station is set into a mahogany finished cabinet and hard rubber top, complete with 2,000 Ohm Brandes Superior Head-set, at our lowest possible price, $20.00 for March. This outfit is well worth $50.00 to you.



Send 6c. Stamps for 156 Page Wireless Catalog

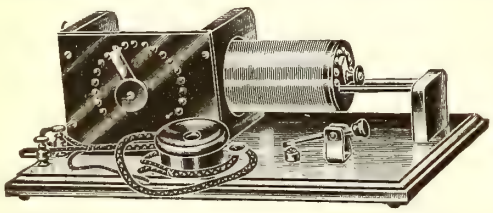
You need this new book, "Radio Stations of the World." A complete authentic list of call signals of every public wireless station. Price, only 50c.

NICHOLS ELECTRIC CO. 1-3 West Broadway, New York

"QUALITY" is our Wireless Watchword

SATISFACTION GUARANTEED OR MONEY REFUNDED OUR MOTTO

Mesco Rotary Spark Gap

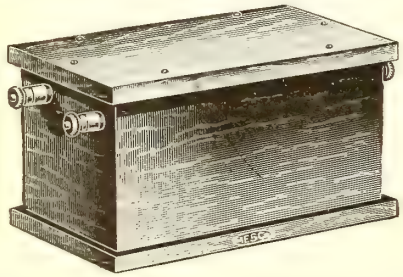


Emits a high musical note. Can be heard at greater distances than the note from the stationary type. Cannot be mistaken for static or other atmospheric disturbances. Produces pure wave of low damping decrement. Increases transmitting efficiency 20 to 30 per cent.

The rotating member has twelve sparking points mounted on a hard rubber disk and is carried on the motor shaft. Can be used on our spark coils or transformers up to 1 K. W. Has two stationary electrodes with special adjusting devices.

Our Globe Motor is used. Will operate on 110 A. C. or D. C. circuits; speed of 4,500 R.P.M. Also made with our Globe Battery Motor, which can be operated on a six-volt circuit.

List No.		Price.
222	Mesco Rotary Spark Gap, 6 volt	$12.00
223	Mesco Rotary Spark Gap, 110 v., A. C. or D. C.	13.00
216	Rotary Unit Only, with two Stationary Electrodes for 3/16 in. shaft	5.00

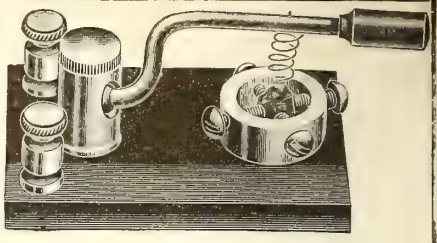


Manhattan Wireless Receiving Set

Consists of a loose coupler, fixed condenser detector, and an 80 ohm receiver with cord. Will tune up to 1,800 meter wave length on a 60-foot aerial. Can be tuned to waves over 4,000 meters with larger aerial and properly connected to loading inductance and variable condenser shunted across the secondary of the receiving transformer.

List No.		Price.
210	Manhattan Wireless Receiving Set	$10.00

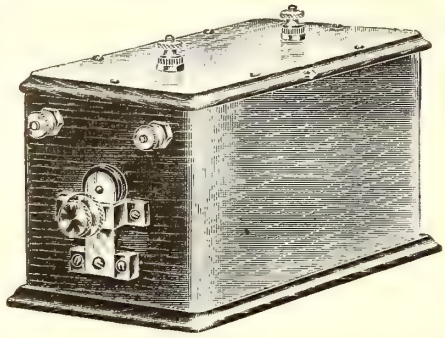
Mesco Intensifying Transformer



Used for intensifying signals received from any crystal detector by connecting an audion detector on the other side of the transformer winding. Used between two audion detectors, signals will be intensified 10 to 25 times.

As many as three of these transformers can be connected between audion detectors in cascade, forming an intensifier, making it possible to read signals not heard with any single known detector. Diagram of connections with full directions with each instrument.

List No.		Price.
224	Intensifying Transformer	$12.00



Mesco Universal Detector Stand

Has a heavy brass cup, with four binding screws; will hold crystals up to ¾ in. diameter. A hollow standard encloses a brass ball. Through an opening a brass arm with hard rubber handle is secured fast to the ball, making a ball and socket joint, allowing it to be adjusted at any angle or used in any position.

Hard rubber base 2¼x4¼x⅜ in. All metal parts nickel-plated. Remains permanently in adjustment under jars and vibrations of every description.

List No.		Price.
248	Mesco Universal Detector Stand	$3.00

Mesco Wireless Spark Coils

Have low current consumption. Best to operate on dry batteries. Contact points of heavy platinum iridium. Has primary condenser in case. Made for wireless work. Permits of close tuning. Spark at interrupter reduced to a minimum; spark is heavy; made in ¼-inch to 4-inch sizes. Our Manual gives all the technical points.

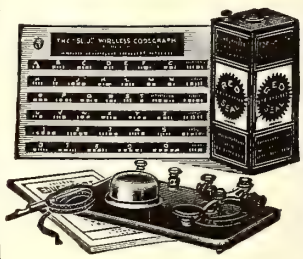
List No.		Price.
462	Spark Coil, 1 inch; can be operated on 6 Red Seal dry batteries	$5.40

Send 10c. for Copy of Our Wireless Manual No. 9

YOU GET YOUR MONEY BACK ON AN ORDER OF $1.00

It contains 120 pages and tells how to erect and maintain wireless telegraph stations. Shows a number of diagrams. Has the Morse and Continental Telegraph Codes. Illustrates the best instruments to use; tells what they are for and how to use them. Has many new diagrams and other valuable information not contained in any other book. Do not wait. Send your request now.

Get the Best 10c. Value You Will Ever Buy



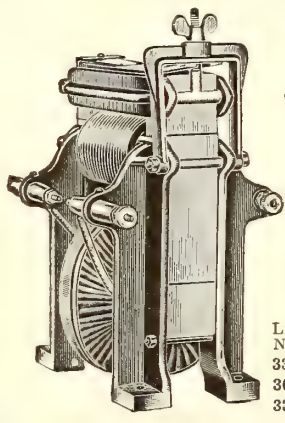
SEND FOR OUR POCKET CATALOG, W 28

It contains 248 pages, 1,100 illustrations and costs you nothing.

IT MEANS MONEY SAVED TO YOU

to have our Manual and our Catalog when you want to buy.

Mesco Codegraph



A dandy practice set for the beginner. Just the right kind for the apt boy.

The Codegraph Plate is of metal with insulated dots and dashes. The Pen is connected with the Red Seal Dry Battery and the Wireless Practice Set. When the pen is drawn across the dots and dashes it closes the circuit, and the buzzer sounds. It is possible to attach a sounder to the outfit and get the telegraph click also. A practical and efficient way of learning wireless and telegraph signals.

List No.		Price.
303	Mesco Codegraph Set	$2.50
304	Codegraph Plate, Pen and Book	1.00

MANHATTAN ELECTRICAL SUPPLY CO.

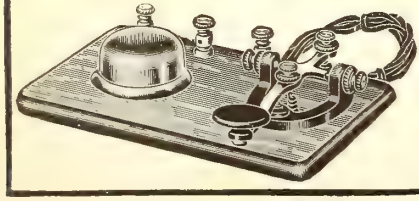
New York, 17 Park Place. Chicago, 114 S. 5th Ave. St. Louis, 1106 Pine St.
San Francisco Office, 604 Mission St.

Mesco Flexible WIRELESS TRANSFORMERS

Will make wireless apparatus 200 per cent. more efficient. When short circuited or when charging condensers does not consume any more power than the magnetic shunt is set for. Can be connected direct to alternating circuit.

List No.	Capacity.	Secondary Voltage.	Price.
330	½ kw.	5,000 v.	$15
363	¾ kw.	10,000 v.	20
331	1 kw.	20,000 v.	25

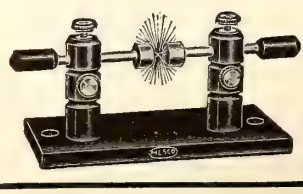
Mesco Wireless Receivers



Have powerful field magnets and thin diaphragms, and are very sensitive. Our No. 480 Double Head sets complete have been used in receiving commercial wireless messages over distances of 2,000 miles. All receivers are wound with silk covered copper wire.

Best steel obtainable used in construction of the permanent magnets. Users have had head sets for five years and over without any deterioration in sensitiveness. This cannot be said of any light-weight receivers.

List No.		Price.
480	Double Head Band, with six-foot green silk cord and two receivers, 1000 ohms each	$6.00



Mesco Wireless Practice Set

Comprises a regular telegraph key, without circuit breaker, a special high pitch buzzer, one cell Red Seal dry battery, and four feet of green silk-covered flexible cord. The main object of the set is to enable the beginner to master the wireless code, and the buzzer reproduces the sound of the signals of the most modern wireless stations perfectly.

List No.		Price.
342	Wireless Practice Set, with battery and cord	$1.88

Mesco High Efficiency Spark Gap

Adapted for stations up to ¼ K.W. capacity. Base is of polished hard rubber. Standards are of hard rubber composition of the highest insulating properties. Hard rubber ends on the brass rods permit the length of the gap to be varied, while sending. Spark terminals are of zinc, and are renewable.

List No.		Price.
465	High Efficiency Spark Gap	$2.80

The Future of Wireless

AT the present state of the art, Wireless can be sub-divided into three classes:

1st. Wireless Telegraphy or Radiotelegraphy.
2nd. Wireless Telephony or Radiotelephony.
3rd. Wireless transmission of Power. The latter we may term as *Radiokinetics.*

As is well known, the first two are already in every-day use, all over the world. The third is as yet undeveloped, but already it looms large above the horizon.

Like all great things, Wireless has had its share of trials and tribulations. It takes time to develop an entirely new art. Moreover, Wireless received a black eye in its earliest infancy in this country. As will be recalled, a number of unscrupulous individuals unloaded millions of dollars of worthless stock on a credulous public, before the art had sufficiently advanced to make possible a successful commercial exploitation.

Practical commercial Wireless Telegraphy is not much older than ten years to-day. Commercial Radiotelephony has but made its appearance during the past one or two years, while Radiokinetics does not exist at all as yet.

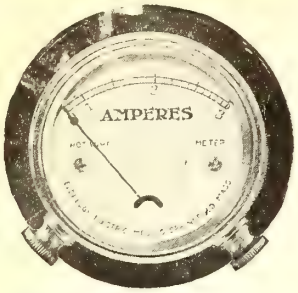
But let us consider how the three classes of Wireless line up as far as their ultimate usefulness and commercial practicability are concerned. Let us look the problem square in the face and let us see what we shall find.

It is our opinion that a purely Wireless Telegraph Company can never reach such immense proportions as our wire telegraph companies. The reason is obvious. The wire telegraph companies are too well intrenched to be driven out of the field; it is quite certain that wireless telegraphy can no more hope to supersede wire telegraphy, than the telephone superseded the wire telegraph. Aside from this it seems hopeless for any one large central wireless plant to send out and receive within a single hour, 8,366 separate messages, as is the case for instance with one of the New York offices of the Western Union Telegraph Company. Wireless will probably never lend itself to such exploitation. Its greatest use will always be long distance transmission of intelligence, either over land or water or both, and between land and ship or vice versa, or between ships. This is its true field and here the wire companies cannot compete. This naturally limits its possibilities. Thus, while the future of Wireless telegraphy does not seem too rosy, we need not feel discouraged. The young man who embarks in radiotelegraphy to-day, will use it only as a stepping stone towards something infinitely greater. This was the exact case of E. N. Vail, the present head of the American Telephone and Telegraph Co., popularly known as the Telephone Trust. Vail was originally a telegraph man when he was called in by Bell and his associates; had he not known all about telegraphy he probably would not be the president of the huge corporation to-day.

This brings us to Radiotelephony. To us there does not seem one field in the entire electrical industry that is destined to a greater and speedier development than this one. We venture to say that within the next fifteen years, Radiotelephony will become one of the greatest electrical industries, for it supplies one of the predominating wants of the times.

The radiotelephone can be used by anyone, just as easily as the wire phone. To operate the instrument it is only necessary to take down the receiver and talk. But three months ago it was demonstrated that it is eminently practical to catch the wireless voice—on the wing as it were—and connect it with an existing wire telephone line. Vice versa, President Vail talked into a wire telephone at New York, where his voice was transmitted to Arlington; here it "took wings" and was wafted without wires to Honolulu, some 4,000 miles distant. This accomplishment more than anything else has opened the public's eyes.

We prophesy that in less than 15 years every automobile, whether pleasure or commercial, will carry its small radiophone outfit. Its occupants will thus be in constant touch with their homes or offices and vice versa, a convenience much needed to-day. Imagine the immense usefulness of such a device. Nor is this an idle dream. There is at least one company in existence to-day capable of filling an order to equip autos with radiophones having a 20 mile range. Nor will there be much confusion of voices becoming mixed up in transit; our tuning apparatus is becoming more accurate each day and it will be an easy matter to tune out unwanted voices. It will take considerable capital and a host of trained men to turn out enough radiophones to equip several million automobiles, aeroplanes, motor-boats, yachts, and large vessels, but it will be done nevertheless and soon at that. Every farmer will have his Wireless Telephone to talk with his neighbors. Every train will have its radiophone enabling passengers to talk to their homes or offices. The radiophone will link moving humanity with the stationary one, the same as the wire telephone linked humanity together before. To us there is nowhere a brighter future than in the vast possibilities of the Radiophone.



As to Radiokinetics, this will surely follow the Radiotelephone in due time. Its future is probably even brighter than the latter. Already Tesla speaks of transmitting energy by the thousands of horsepower wirelessly. Who dares predict what this branch of wireless will bring during the next twenty years?

H. GERNSBACK.

THE ELECTRICAL EXPERIMENTER is published on the 15th of each month at 233 Fulton Street, New York. There are 12 numbers per year. The subscription price is $1.00 a year in U. S. and possessions. Canada and foreign countries, $1.50 a year. U. S. coin as well as U. S. stamps accepted (no foreign coins or stamps). Single copies, 10 cents each. A sample copy will be sent gratis on request. Checks and money orders should be drawn to order of THE EXPERIMENTER PUBLISHING CO., INC. If you change your address notify us promptly, in order that copies are not miscarried or lost. *A green wrapper indicates expiration.*

All communications and contributions to this journal should be addressed to: Editor, THE ELECTRICAL EXPERIMENTER, 233 Fulton Street, New York. Unaccepted contributions cannot be returned unless full return postage has been included. ALL accepted contributions are paid for on publication. A special rate is paid for novel experiments; good photographs accompanying them are highly desirable.

New De Forest Audion Detector

THE BEST AUDION DETECTOR EVER OFFERED FOR PRIVATE USE

¶ The Audion Detector is the most sensitive detector in existence. (Bulletin U. S. Bureau of Standards, Vol. 6, No. 4, Page 540.) The new and improved forms are more sensitive, more reliable and more adaptable than ever before. The new Type RJ8 Audion Detector represents the greatest value for the money ever offered.

¶ It is equipped with **potentiometer** control for the high voltage circuit, giving extremely close regulation which is so essential to obtaining utmost efficiency with the Audion. It is a **panel type** instrument of the very best construction. It is thoroughly reliable and constant in operation, is not affected by mechanical vibration or by the transmitting spark, and is **always** to be depended upon for reception of signals over the greatest possible ranges.

¶ It is worth a stamp for you to be informed on this and the other new DeForest instruments.

The Utilization of the Sun's Energy

Years Ago Man Endeavored to Make Practical Use of the Energy Contained in the Sun's Rays—Even Tesla, the Electrical Wizard, Has Patented a Sun Motor, While the Shuman-Boy's Engine and Sun Boiler Has Developed 100 H. P. There Is Great Promise Held Forth to Future Engineers Who May Work on This Problem.

IT has been given to astrophysicists to measure the heat generated by the sun and calculate the force emanating from it. We know that the surface of our luminary gives out a heat estimated to be about 6,000° centigrade, and that its light equals that of 27,000,000,000 candlepower a quarter of a mile away. The heat which the earth receives from the sun in the course of a year would suffice to melt a belt of ice about 55 yards in thickness extending clear around the earth. Only the 2,735-millionth part of the total energy given off by the sun reaches our earth and, if this were lacking, our planet, with all its thousandfold life, its thick forests and fruitful plains, would turn into a dead, rigid ball of rock, for the average annual temperature, which is now one of 13° centigrade of warmth for Europe, would, without the heat of the sun, sink to 73° centigrade of frost, it is calculated.

A Successful 100 H.P. Sun Power Plant Located at Meadi, on the Nile, Egypt.

Every sort of light with which we illuminate our home when the greater light has sunk beneath the horizon, every fire that warms us when the solar rays can no longer do so, is a product originating in the sun. The chip of wood with which the untaught son of nature brightens his hut, the twigs with which he stokes his fire, what are they but pieces of trees that grew in the sunlight? The gas of the city dweller, the coals with which he heats his house and from which the gas has been sucked, what are they but transformed sunbeams? The coal in the grate is the petrified wood of perished forests that covered the earth's surface millions of years ago, and flourished in the rays of the same sun that ripens our corn to-day. Petroleum, that mysterious earth-oil, comes from the bodies of millions of dead and

gone animals, chiefly natives of the sea, which lived in the gray ages and fed on things growing in the sun. Alcohol is also a plant product, and the candle our ancestors took to be an ideal light, is won

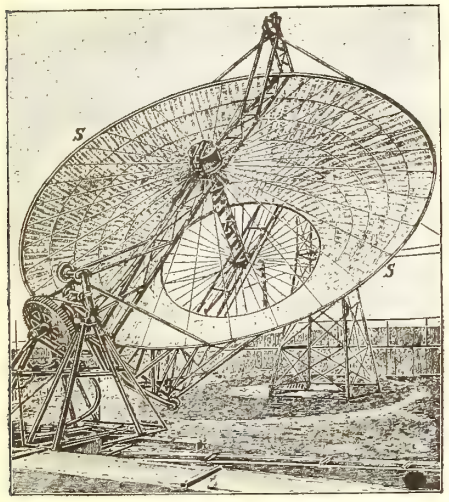

Fig. 1. Common Form of Sun Motor Adopted by Experimenters, Utilizing a Large Number of Mirrors and a Central Boiler.

from the animal and plant kingdom. The smoking fish oil lamps of the Eskimo are indirectly dependent on the sun for their fuel. And what of our own electric light? The dynamo developing the electricity is driven by steam, and the steam engine has to be fed with coal or with other materials gained from the animal and plant kingdoms. How about the waterfall? It would not exist if the sun did not suck up water from the earth's surface, and which is again deposited on the earth in the form of rain.

If it were rendered possible to use the sun's heat itself for the firing of furnaces an ideal state of affairs would be attained. There was a sun motor used for some time on an ostrich farm (see Fig. 1) in South Pasadena, Cal. This consisted of a concave mirror made of single glass planes set together, and measured about 12 yards in diameter. The sun's rays were collected and focussed on to a water tank, let into the mirror in the shape of a cylinder, 2½ yards long, which acted as its axis. When the water tank remained empty on a sunny day its walls grew red hot in less than an hour. The 400 quarts of water it contained was brought to the boiling point in 15 minutes and the steam developed drove a motor of 10 horsepower, which in turn worked a pulley raising 5,600 quarts of water per hour; a decidedly noteworthy performance.

The temperature of the sun, as aforementioned, has been calculated to be about 6,000 degrees centigrade. Several authorities point out that this terrific heat therefore precludes any possibility of the sun being a molten mass in the process of combustion. It has been thought recently by many to be a great mass of matter possessing to a remarkable degree radio-activity akin to radium. Helmholtz proposed that the sun could keep on producing energy at its present rate by accounting for same on the basis of a slight annual shrinkage in its size. From observations and measurements of this heavenly body made from year to year it has been computed that the age of the sun would, on the shrinkage basis, be 17,000,000 years.

The radiant energy received from the sun at the outer surface of the earth's atmosphere is equivalent to 7,300 horsepower per acre. Of this about 70 per cent. or, roughly speaking, 5,000 horsepower per acre, is transmitted through the atmosphere to the land surface proper of the earth, at noon on a clear day. Lesser amounts, of course, are received in the early morning and late afternoon, owing to the greater thickness through which the energy must pass.

Relative to the basis upon which solar energy is calculated for the earth's surface, this is generally made, it may be said, on the "solar constant," as it is termed, ascertained from 696 tests conducted by the Smithsonian Institute of Washington, in various parts of the world, which resulted in accepting 1.93 calories per square centimeter per minute, equal to 7.12 British thermal units per square foot per minute. This is an average value, all things considered.

Only about three-fifths of the solar radiation produce any impression on the earth, and it is only the radiant energy which falls on some material body that is converted into heat. The best body for this conversion having been ascertained to be a dead black one.

Many scientists and philosophers in the past century have tried various methods by which to concentrate the sun's rays, such as schemes utilizing an immense number of lenses built in the form of a huge cone, as previously described and illustrated at Fig. 1. A European experimenter in the year 1820 constructed one similar to this, but on a small scale. This model concentrated the rays sufficiently to melt tin at a distance of 68 yards from the apparatus, and also it was possible to cook food and melt silver instantaneously.

In the year 1882 a Frenchman by the name of M. Pifres devised a solar engine which was built on the roof of a building in Paris to drive a printing press, and the paper so published was called the "Soleil Journal." Capt. John Ericson experimented with solar engines from 1868 to 1886 with more or less success, but nothing remarkable or practical was developed. Another early worker was A. G. Eneas. His solar engines are described in United States patents issued in 1901, bearing the numbers 670,916 and 670,917.

Getting down to basic and simplified apparatus for utilizing such radiant energy as that possessed by the sun's rays, both visible and invisible, we may consider the apparatus of this nature devised by Dr. Nikola Tesla, the well-known electrical scientist. His United States patents on "Apparatus for the Utilization of Radiant Energy" bear the numbers 685,957 and 685,-958. This apparatus, intended to absorb and transform such radiant energy as that given forth by the sun, is shown in the illustration at Fig. 2.

Tesla says of this matter that his own experiments and observations have led him to the conclusion that such sources of radiant energy as the sun throws off with great velocity, minute particles of matter which are strongly electrified, and are, therefore, capable of charging an electrical conductor, or, if not so, may at any rate discharge an electrified conductor either by carrying off bodily its charge or otherwise. His patents in this direction are based on alleged discovery by him that when such rays or radiations are permitted to fall upon or impinge against an insulated conducting body P connected to one terminal of a condenser, such as C in Fig. 2, while the other terminal of the condenser is made by independent means to receive or carry away electricity, a current flows into the condenser so long as the insulated body P is exposed to such rays; so that an indefinite, yet measurable, accumulation of electrical energy in the condenser takes place.

This energy, after a suitable time interval, during which the rays are allowed to act in the manner aforementioned, may manifest itself in a powerful discharge, which may be utilized for the operation or control of a mechanical or electrical device consisting of an instrument R, to be operated and a circuit-controlling device d (Fig. 2-A).

Tesla bases his theory on the fact that the earth is negatively charged with electricity and he considers same to act as a vast reservoir of such a current. By the action of the sun's rays on the plate P there is an accumulation of electrical energy in the condenser C. A feeble current is supposed to flow continuously into the condenser and in a short time it is expected to become charged to a relatively high potential, *even to the point of rupturing the dielectric.* This accumulated charge can then, of course, be used to actuate any device desired.

An illustration of a proposed form of apparatus which may be used in carrying out his discovery is referred to in Fig. 2-B. In this figure, which in general arrangement of the elements is identical to Fig. 2-A, the device d is shown as composed of two very thin conducting plates, t t^1, placed in close proximity and very mobile, either by reason of extreme flexibility or owing to the character of their support. To improve their action they may be enclosed in a receptacle from which the air may be exhausted. The plates t t^1 are connected in series with a working circuit, including a suitable receiver, which in this case is shown as consisting of an electromagnet M, a movable armature a, a retractile spring b and a ratchet-wheel w, provided with a spring pawl r, which is pivoted to armature a, as illustrated. When the radiations of the sun or other radiant energy source fall upon plate P a current flows into the condenser, as before explained, until the potential therein rises sufficiently to attract and bring into contact the two plates t t, thereby closing the circuit connected to the two condenser terminals. This permits a flow of current which energizes the magnet M, causing it to draw down the armature a and impart

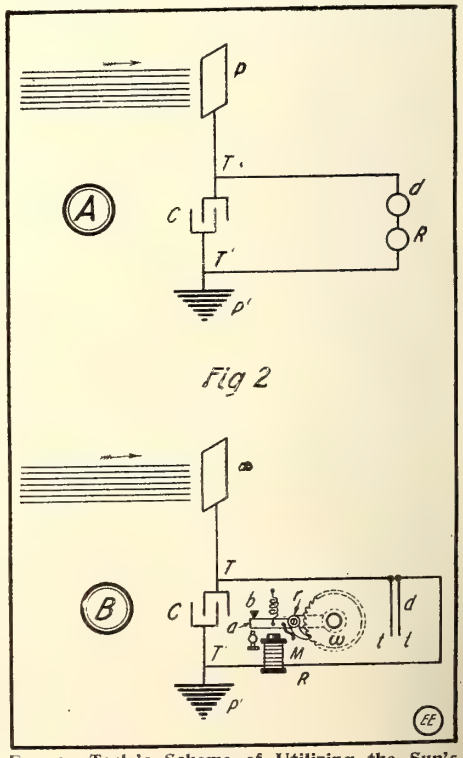

Fig. 2. Tesla's Scheme of Utilizing the Sun's Energy.

(*Continued on page* 662.)

The Choralcelo, a Wonderful Electric Piano

This Marvelous Electrically Operated and Controlled Musical Instrument Is More Than a Piano—It Produces Sustained Notes of the Lowest and Highest Register Over a Range Heretofore Unattainable, and, Moreover, Is Played Like a Regular Piano

IN India, far away, as the popular song goes, the natives are content to regale themselves musically with the plaintive notes given forth by a goat skin stretched over the end of a hollow log, upon which the musician beats a tune with the flat of his hand.

The music of the cavemen was the wind sighing through the trees, accompanied by the rustle of the leaves. Even they wanted to express themselves in a harmonious manner, hence the drum, the horn and other crude instruments of musical expression.

Then we may possibly expect some marked advances in our musical culture and education since the advent of he "Choralcelo," despite the prophecies of those who take a pessimistic view of life in general.

The piano becomes a tongue-tied infant beside this latest masterpiece of the musician's art. At times its notes thunder forth and seem to shake the very earth itself, and then again they may be subdued to an elusive softness like unto the faint notes of a distant church choir.

But what is it? How is it accomplished? What is the result of many years of untiring labor on the part of several of the cleverest men of the world? What is it on which a fortune that would ransom a king has been spent? The Choralcelo!

The Choralcelo, the most wonderful musical instrument ever thought out by the human mind, is like nothing else the world of music has ever known. This masterpiece reproduces any piece of music in any form of instrument, from a string to a flute; not only does it reproduce them, but the notes emitted by it are sustained, pure and sweet, which is entirely different from the ones produced by the instruments that are in present use.

Practically all the musical instruments, previous to the invention of the Choralcelo, carry into the tone which they produce certain impurities which arise from the manner in which they are caused to vibrate. The violin interrupts the free vibration of the string by the grating rub of the bow. The piano adds the noise that results from the blow of the hammer on the string—while the organ mingles the *breathiness* of its air current with the pure vibration of the column of air within the pipe. In like manner all instruments employing extraneous contacts to start the vibration destroy the purity of the note produced. And as they seek to amplify the tone that they have produced they increase the intrusion of extraneous and false sounds. The soft pedal of the piano, the swell-box of the organ, the mute of the violin, are just so many outrages on the purity of the tone.

The Choralcelo, by the very means which it employs in producing the tones, is freed from all obstructions. Vibration without contact, involving *perfect freedom of vibration,* and thus the Choralcelo gives all the natural overtones and harmonics; rich—full—pure and perfect, thus opening to the musician wonderful possibilities of expression and emotional power of which he possibly never dreamed.

The manner in which this result is accomplished is one of wonder. It is the subtle pull of the electro-magnet which now achieves pure tone production. These electro-magnets are caused to act directly upon the strings of the instrument.

The most delicate graduation of tone power can be produced by the mere variation of the strength of an electric current, and not by *smothering* devices which the present form of instrument employs. The tone, therefore, retains all its original purity through all vibrations and intensity, something which has been impossible heretofore.

We will next inspect the mechanism employed to perform these wonders. It may be stated that the vibrating elements are caused to oscillate by means of a pulsating electric current sent through an electro-magnet acting on the vibrating membrane. The machine which breaks up continually the electric current into a series of waves is really the "heart" of the Choralcelo. The operating device consists essentially of a series of metal discs having a certain number of insulating segments inserted in their peripheries. These discs are arranged to revolve at a fixed speed. Silver-tipped brushes are so placed that they will bear upon the revolving discs. It will thus be seen that in order to produce the fundamental periodicity of any given "string" it is only necessary to rotate a disc containing a certain number of segments at the correct speed.

A large variety of combinations are possible through the manipulation of a few keys, which correspond to the stops of an organ, and such a keyboard is clearly shown at Fig. 1. This resembles a piano, and it really is one, with additional keys and pedals. The pedals are used to vary the strength of the current sent through the electro-magnets.

A tremolo effect is given by means of a slow speed interrupter giving a pulsating current at a few revolutions per second. The instrument which produces this effect is depicted on the right of Fig. 2, while the one toward the left reproduces tones representing a flute. The regulation piano tone is produced with the usual percussion hammers, which may be thrown into or out of action by the pressure of a key. The staccato notes of the piano may be struck upon strings already vibrating with the pulsating current. Thus sustained notes of a higher pitch are produced upon the string. A piano which employs both the electro-magnets and hammers is clearly shown on the left of Fig. 3. Note the large number of wires which are employed for connecting the various magnet coils. It is an engineering feat in itself to even make and wire the various circuits.

Marvelously sweet tones are produced by vibrating pieces of brass, wood and aluminum. In fact, any resonant body susceptible to vibration may be made to emit tones. In order to cause these bodies to vibrate it is

New Uses for Electricity in the War

MICROPHONE NOW DETECTS MINE SAPPERS.

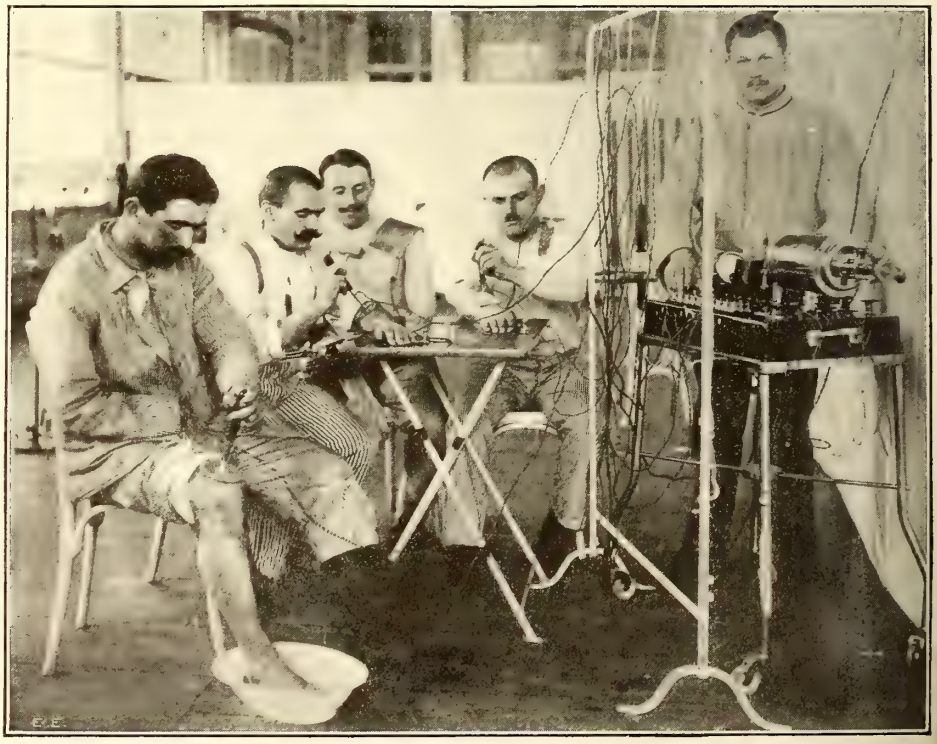
Electricity has been utilized to an unimaginable extent in the present titanic struggle across the ocean. In the interesting illustration shown herewith we see one of the latest adaptations of this wonderful agent of man and involving the microphone. The microphone, the electrical instrument which will pick up a delicate sound and transmit it in the form of undulating electric currents over a circuit, has solved many an important problem in the past, and especially during the present war.

How French Mine Sappers Utilize the Microphone to Hear the Germans Counter-Mining by Sound Conduction Through the Earth.

The two men at the right of the illustration are seen in the act of listening for German mine "sappers," and the men here shown are French. They, as you will note, are wearing shrapnel-proof metal helmets. A small box contains the batteries, etc., and the soldier leaning forward and listening so intently has in his hand a small but delicate watch case telephone receiver which is connected with the wires running along the wall to a supersensitive microphone placed in contact with the earth wall of this underground passageway. The French sappers are running a counter-mine out of the entrance of which one of the men is looking, as perceived at the right of the illustration.

It is indeed remarkable to what distances such sounds as those produced by pickaxes and shovels can be propagated through the soil. The sound conduction is also enhanced wherever rock or mineral formations are present to any extent in the earth. While the opposing sappers may explode their mine and blow up the French soldiers here observed resting so contentedly in the act of writing letters home, there is some consolation in knowing that they have a fair chance to climb out of the underground passage before the German mine has been driven far enough to do any damage, thanks to electricity.

TO BUILD NEW MARCONI TOWER AT CAPE MAY, N. J.



Sherman Sharp, a contractor of Cape May, N. J., has been awarded the contract to build the new building for the Marconi Wireless Telegraph Co. at Cape May. The building will be located about a half mile back from the shore on the site of the city water works.

The City Commissioners have leased the property to the Marconi company for 10 years, and the operation of erecting a tower 140 feet high will be started immediately.

HOW ELECTRICTY AIDS GERMAN SOLDIERS TO GET WELL.

The rigors of a hard winter in the trenches, besides the stiffness and other muscular complications resulting from bullet and shell wounds, are bound to show up in the sturdiest soldier sooner or later. Another important factor to be reckoned with in modern warfare is the tremendous nervous strain under which the men labor during or even before the actual fighting, owing to the heavy cannon and gun fire, as well as that of the machine guns, etc., which results in nervous exhaustion, and indeed in some cases in complete collapse.

In this event the soldiers so affected are invariably sent to the rear or to the nearest field hospital, if properly equipped for treatment of this kind. In the illustration herewith a number of convalescent German soldiers are observed taking treatment from a specially designed electro-therapeutic machine, supplying current of a certain frequency and strength. The current produced by this particular machine may be so regulated, when desired by the operator in charge, that it will have the characteristics of the well-known Faradic current, used extensively in the treatment of rheumatism and like complaints. Again the current may be specially controlled and regulated to the proper frequency and wave form adapted especially for the treatment of nervous exhaustion previously mentioned, which ailment, by the way, has been more noticeable in the present war than in any previous conflict.

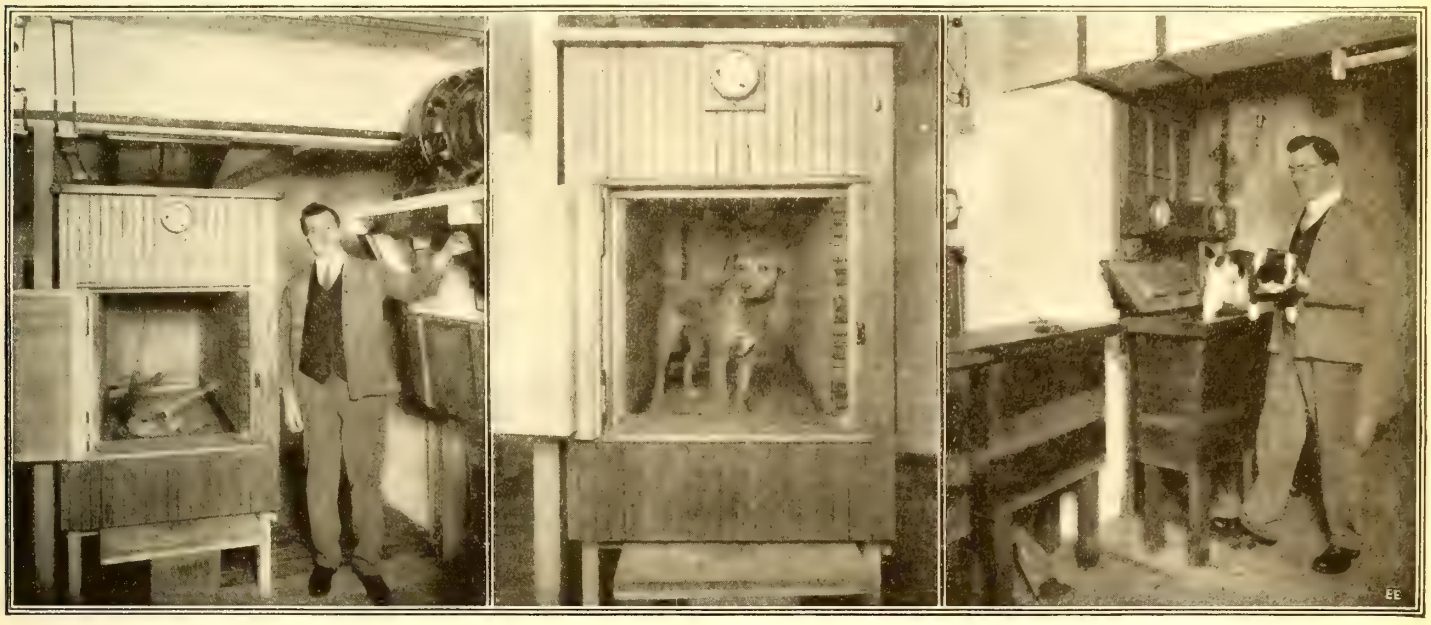
German Soldiers Undergoing Electrical Treatment for Stiffened Muscles, Nervousness and Other Ailments.

AGING WINE BY ELECTRICITY.

A method of "aging" raw wines and spirits by electricity has been perfected by Professor Charles Henry of the University of Paris (the Sorbonne), and it is already being successfully used in some of the Burgundy wine districts. The process is said to impart to liquors the same properties which they acquire by being kept for a number of years in cellars. The spirit or wine is placed in a special receptacle fitted with two tubes called "purgers," and the tubes are charged with high tension electricity at from 60,000 to 120,000 volts. The result is that all the bacteria, ferments and impurities collect in the tubes and are removed and all further ferment tion is stopped. The process is very rapid, and the cost is less than two cents per hundred gallons. Similar experiments are now being made with beer and essential oils.

Electrocuting Superfluous Cats and Dogs

WHEN your favorite Tabby or Fido strays away or is turned out for good you would like, doubtlessly, to see it killed as humanely as possible, if that is to be its end; and killed all such animals invariably must be, especially in large cities, where the total number of unclaimed pets gathered up by the authorities is truly astonishing.



Electrocution, now widely adopted in various State prisons, has been happily incorporated in the latest apparatus employed by the Animal Rescue League of Boston, Mass. The illustrations here shown and reproduced through the courtesy of Huntington Smith, director of the above association, depict the electrical apparatus used for rapidly and painlessly killing such unlucky quadrupeds. Besides the apparatus installed in Boston for this purpose, there have been similar outfits adopted by over twenty other cities, which in the past five years have helped to destroy an unbelievable number of such animals.

In the year prior to 1915 there were destroyed no less than 480,848 small animals by 252 humane societies and their agents. In the past and, of course, to a very large extent at the present time there are several different methods employed for disposing of superfluous animals of different kinds, but mostly cats and dogs which are turned out of homes when people move away, etc. Among these methods are those involving the use of poison, chloroform, carbon monoxide, illuminating gas and shooting. None of these methods is in any way as humane as the new electrical method for exterminating such animals. The electrocuting outfit was first installed in the Animal Rescue League of Boston in 1911. It possesses all the best features recommended by those in charge of this kind of work, besides being highly recommended and advocated by many members of the medical profession who have looked into the subject deeply and who believe that life is cut off before any pain can be felt.

In the illustrations herewith we perceive (the center photo) how a dog is placed in one of the electrocution chambers. This cabinet measures about 2 feet 6 inches wide by 6 feet long and stands 4 feet 6 inches high. It is so mounted that it is at all times convenient for the operator to place the animal in the chamber. A metal pan is placed in the electrically insulated inner cabinet, while above it is fastened at either side; there is mounted a metal bar from which is suspended a strong spiral spring fitted with snap hooks at the free end. The lower electrode or pan is joined to one pole of a high-tension transformer, and the metal rod carrying the spiral spring electrode to the other high-tension pole. When the door of the cabinet is open the transformer primary is automatically opened also, to protect the electrocutioner; but when the door is closed the primary circuit of the transformer is completed. A flexible metal collar fitted with suitable electrode points is placed around the dog's neck and the spiral connection is hooked up to the collar. This stage of the electrocution is seen in the center illustration, with the animal alive, standing in the metal pan. In a second's time the door is closed and the dog receives the full strength of the electric current, which is believed from careful observations to kill him instantly, so that no pain whatever or torture is experienced. The illustration at the left of the group depicts the dog after electrocution.

In the illustration at the right the electrocutioner is seen holding the remains of an extinct feline. The apparatus for doing away with cats electrically is fitted up with metal electrodes hung at either end of a slate tray. The top of the cabinet automatically operates the transformer circuits, as in the case of the machine previously described. The cover is rigged up with a foot treadle so that by the pressure of the foot the top may be opened or closed, thus leaving both hands free with which to manage the animal, for, as most of us know, it requires some skill and agility to put a cat in a box or bag. The cat is grasped firmly with both hands and is then placed in the box or cabinet so that its fore feet rest on one electrode, while the hind feet rest on the other. The instant the cover is closed the high voltage is passed through the body of the cat and it is rendered unconscious or dead instantaneously. Peculiarly enough, it has been ascertained that cats require about twice the length of time necessary to electrocute dogs. Contrary to the reader's probable impression, this is not believed to be due to the proverbial nine lives accredited to the feline, but to its inherent vitality, to its higher organic resistance to the electric current and also to variations in the contact made, depending on the dryness of the skin.

A most interesting fact in connection with the electrocution of these animals is that the current when first switched on rapidly reaches a maximum and then falls off to about one-half of this value. The voltage employed for this work varies from 4,000 to 5,000. It is believed that a much lower potential will do the work in a satisfactory manner, but so far such tests have not been made, due mainly to humanitarian reasons. One kilowatt-hour of electrical energy will suffice to kill from 800 to 1,000 animals, it is said. An alternating current has also been found to be the best for this work.

Electrocuting Cats and Dogs at the Animal Rescue League, Boston, Mass. The Most Humane Way in Which to Kill Superfluous Pets.

ELECTRIC LAMP THE BEST READING LIGHT.

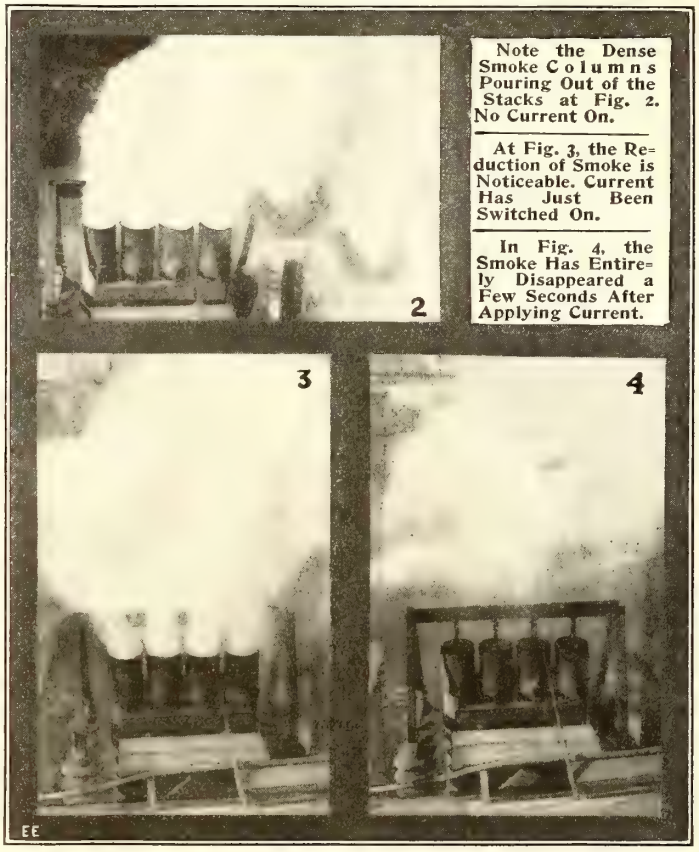
Recent scientific investigation has shown that the reading lamp which is equipped with the proper electric incandescent light and shade is superior to any other form of lamp for reading purposes. The essential features of this lamp are that the incandescent bulb is all frosted and that the shade is so arranged as to protect the eye from the direct light of the bulb.

One occasionally hears a preference expressed for the kerosene lamp for reading purposes, the statement usually being made that it is easier on the eyes. This is doubtless due partly to force of habit and partly to experience with unsuitable electric lamps.

The brilliancy of the incandescent lamp can be reduced to approximate that of the oil lamp by using an all-frosted bulb. By using a suitable shade the eyes will be still further protected and the light directed onto the book or paper which is to be read and a pleasing color tone may be obtained. The light from the oil lamp is made up principally of yellow, orange and red light, while the incandescent lamp gives much more nearly white light from which by means of proper shades any color can be obtained.

Proper lighting for reading purposes is a big factor in the general health of persons, since eye-strain reacts on the body, causing headaches, nervousness and indigestion.

Killing the Smoke Nuisance Electrically



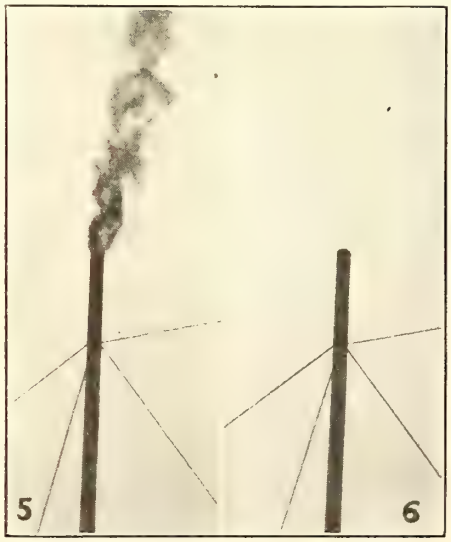
By Samuel Cohen

WE watch the smoke floating upwards from the chimneys of our manufacturing plants with thoughts that differ with the individual. The housewife thinks only of the damage done to her freshly washed clothes. The engineer thinks of the inefficiency of the plant, while the good citizen thinks of the effect such smoke will have on the health of the community. We will not enter into a discussion here as to which one takes the proper or best view, for it is well known that a pure and clear atmosphere is necessary for the health and welfare of a community.

The smoke nuisance has been made the subject of laws in many cities, but the manufacturer was at a disadvantage. No practical or reliable smoke prevention method was within his reach until recently, so that he had to rely on special grates, the use of hard coal or else on expert firing to prevent the levying of fines.

Leading engineers and scientists of this country and abroad have been constantly laboring on this problem, and although some of them have invented schemes for preventing the unnecessary smoke from entering the atmosphere from the stack, yet these were not of commercial value on account of being too complicated. The electrical precipitating method, however, has proved far superior to any other in its operation. The operation of this scheme is described herewith.

The electrical precipitation apparatus was originally devised by Sir Oliver Lodge, but it was finally developed and perfected by The Research Corporation, under the direction of Dr. F. G. Cottrell, the inventor of the present form of this apparatus. Since smoke is nothing more or less than minute particles of carbon and other solids suspended in the air the basic principle of his scheme for precipitating smoke, dust and mist is to charge all the particles in the stack with electricity. In this way they will be collected on the side of the conductor, and as soon as a large quantity of the soot is accumulated, it falls down to the bottom of the stack. A schematic diagram showing the connection of the various apparatus used is depicted in Fig. 1. It will be observed that a transformer is employed for supplying the high tension current. The voltage required depends upon the size and condition of the plant in which the apparatus is to be installed, so they vary from 50,000 to 100,000 volts. The secondary of the transformer is connected to a special rectifier which virtually consists of a rotating arm of four poles connected as perceived in diagram. This arm is revolved at constant speed by a synchronous a.c. motor. One of the stationary terminals is connected to a wire suspended in the stack and properly insulated from it by a high tension insulator. The opposite terminal from the stack is connected to the ground, which consists of a large number of pipes placed in the base of the chimney, while the other two terminals are interlocked with the secondary of the transformer. This rectifier is used to change the high tension alternating current to direct current, which is of extreme importance, as the whole secret of this type of apparatus lies in charging the particles with one kind of charge, so that they may adhere to one of the terminals and are thus prevented from escaping out of the stack. If an alternating current supply is not available, a motor-generator set is employed and the rectifier revolving disk is then placed on its shaft.



Several interesting illustrations are herewith given showing stacks fitted with this apparatus for eliminating smoke electrically. Fig. 2 illustrates such a stack when the current was turned off; note the density of the smoke cloud rising from it. As soon as the current was switched on, the smoke was reduced (see Fig. 3), and a few seconds later it had entirely disappeared, as shown by Fig. 4. Two other striking illustrations which show the marvelous efficiency of this apparatus are portrayed in Figs. 5 and 6; the former depicts the dense smoke issuing from the chimney, while the latter illustrates the appearance of the flue when the current was turned on.

Although the above mentioned apparatus is being extensively employed in the precipitation of smoke, it has also been used

ELECTRICITY ON OCEAN LINERS.

The amount and variety of electrical apparatus carried by any large ocean liner is quite astounding. From the wireless aerial suspended high above the upper deck to the cargo lamps in the lowest hold electricity is in constant use.

The usual electric installation on a large liner consists of four engines and dynamos, each dynamo having a capacity of 400 kw. at 400 volts. There are also auxiliary generating sets, consisting of two 30-kw. engines and dynamos situated on a platform in the turbine engine room 20 feet above the water line. These auxiliary emergency sets are connected to the boilers by means of a separate steam pipe, so that should the main sets be temporarily out of action they can provide current for such lights and power appliances as would be required in the event of emergency. Working in conjunction with these emergency sets is a battery with a capacity of 3,500 ampere-hours, situated on the promenade deck, forward of the first-class smokeroom.

The electric lighting on such a steamer is equal to that of a good-sized town, the total number of incandescent lights being about 11,000, ranging from 8 to 16 candle-power. There are special dimming lamps in the first-class rooms, and the electric bell system includes 1,700 bell pushes and 29 indicator boards distributed all over the vessel, with fire alarm pushes distributed throughout the great liner and an alarm bell and indicator in the chart room.

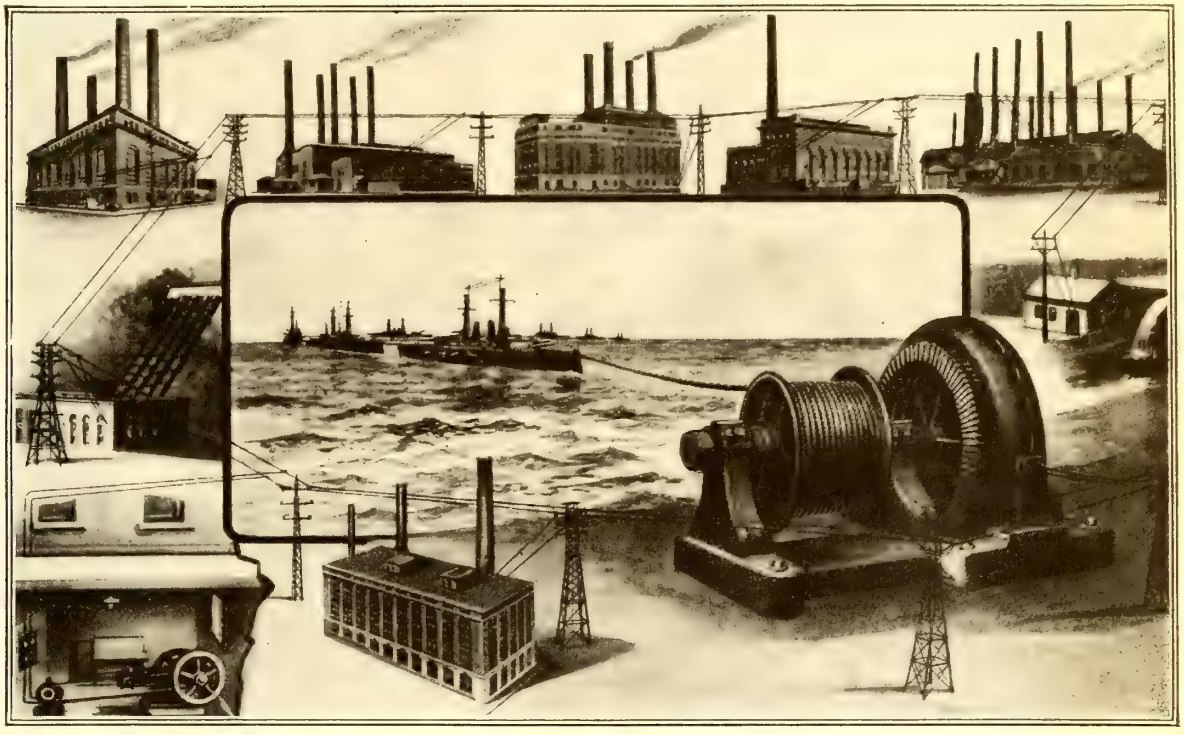
There are electric heating, power and mechanical ventilation apparatus in service, altogether 188 motors and 600 electric heaters being installed throughout. The system of ventilation consists of electrically-driven fans—some suction, others pressure, and in many cases provided with steam coils for warming the air. Loud-speaking telephones of navy pattern are fitted for communication between the wheel house on the bridge and forecastle and after docking-bridge, engine room and wireless room, and also in the chief engineer's cabin.

The telephones are operated both from the ship's lighting circuit, through a motor generator, and alternatively by a stand-by storage battery, which is introduced in the circuit, should the main supply fail, by means of an automatic switch. There is also a separate telephone system for intercommunication between a number of the chief officials and service rooms, through a 50-line exchange switchboard. A number of the pantries and galleys are also in direct telephonic communication.

The apparatus for wireless telegraphy consists of a 5-kw. motor-generator. The house for the instruments is situated on the boat deck. There are four parallel aerial wires extending between the masts fastened to light booms; from the aerials connecting wires are led to the instruments

(*Continued on page* 655.)

What All the Electric Plants in America Could Do



IT was after Watt's wonderful discovery of the power of steam, resultant from observing a tea kettle, it is said, and later terminated in the invention of his steam engine, that people realized its great energy producing possibilities. They then began to build Watt steam engines and used them advantageously for driving their machines. Although this source of power has rapidly increased in use the introduction of the generation of electricity, the internal combustion engine and modern water power developments have revolutionized power plant design and made practical the small, isolated plant. To-day electricity is invariably used in manufacturing plants for light and power, which, in those requiring a large amount of energy, is usually generated by steam driven generators, while gas is used in some of the larger plants.

One cannot conceive of the vast amount of electrical energy that is daily being generated throughout the United States. The following comparisons will serve to make somewhat clearer the great magnitude of the energy developed by all the plants in this country, including those driven by water, wind, etc. If these were connected in a single, continuous circuit with its terminals linked to some device, as a motor or electric lamps, we could then readily observe the effect of this tremendous power.

One of the simplest electrical devices known to the average person is the incandescent electric lamp. If we could obtain a sufficient number of these lamps of the 20-watt size, and string them along a wire line from *the earth to the moon*, the lamps being 15 inches apart, the amount of current necessary to light them would then represent the amount of power generated by all the dynamos in the United States, which in their entirety have an output of about 20,350,000,000 watts per hour.

For another illustration we might stretch a line of two conductors 15 *times around the earth* and place on this 1,000-watt lamps one hundred feet apart. The power required to light this gigantic line would also represent the electrical energy produced by these ever-humming dynamos.

An interesting comparison showing still another effect of this tremendous electrical energy is noted herewith. A fleet *thirteen times larger* than Uncle Sam's navy could be hauled through the water by means of a massive electric motor stationed at some fixed point. The power would have to be supplied from the generators through extremely large conductors, of course, in order to withstand the enormous electric current. The motor would also be of a special design, and of truly gigantic size in order to develop 27,614,766 horsepower. The only difficulties that would probably interfere with such an enterprise would be in obtaining or building transmission line, the motor and a proper foundation. This latter would have to be very strongly built to withstand the torsion when the motor started to haul the vessels.

The Total Electric Power Developed by United States Electric Plants Could Haul a Fleet Thirteen Times Larger Than Uncle Sam's Navy.

Again, if 20,350,000 1,000-watt lamps were connected to a common circuit and grouped in such a manner as to cause their total light to fall upon a concave reflector the total candle power of the light produced by this lamp bank would be about 18,498,150,000, which is enormous, of course, in comparison with the largest lighting displays with which we are ordinarily familiar.

A simpler lighting arrangement than the one before mentioned might be obtained by using two proper sized carbon electrodes, connected to some source of current and operating them as an ordinary arc lamp. The light evolved would be of such magnitude that it would be detected for several hundred miles, of course, but the curvature of the earth is not taken into account in stating this distance. The heat produced by such a scheme would be so terrific that anything known to man would be boiled.

This vast sum of energy is nearly inconceivable.

The "Nokolyd" Motor Car Rear Signal

Our readers will find it worth while looking into the merits of this automobile rear signal, as it is one of the most ingenious of all the automobile devices tested by the Safety First Society.

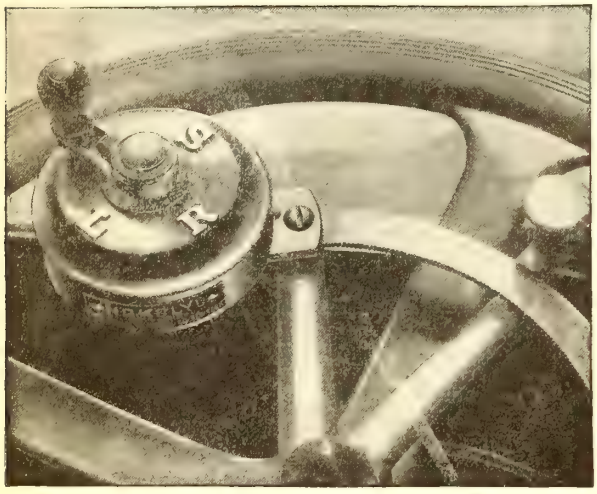


Fig. 1. Control Handle for Operating "Rear" Auto Signal.

The device is electrical. It is operated from the storage battery, which forms part of the equipment of every automobile, or it may be operated by ordinary dry cells. As each signal is set the current is automatically cut off, from which it becomes apparent that the current consumption is very low.

The controlling mechanism (Fig. 1) is fastened to the steering wheel, and within is an automatic stop mechanism which operates in a similar manner to a Postal Telegraph call box. The dust-proof box at the rear has a square member inside with four faces marked "stop," "right," "left" and the fourth space is plain white and shows when the controller is in a neutral position.

When the controlling lever is turned to the letters "S," "R," "L," or "O," the square member in the rear is turned by an electric magnetic device until the face "stop," "right," "left," or blank, corresponds to the letters on the controller. The controller can be turned one complete revolution without stopping at the intermediate letters, and the square member will also turn one complete revolution (Fig. 2).

Fig. 2. How New Auto "Rear" Signal Appears.

The "stop" signal shows white letters on a red background; the "right" signal shows black letters on an orange background; the "left" signal shows white letters on a green background. Both the "right" and the "left" signals are supplemented by arrows showing the direction. By day the signal is plainly visible for a long distance and by night it is automatically illuminated. A tiny bell rings when the signal is given, which informs the operator that the instrument has registered correctly.

FIREMEN AND ELECTRIC POWER LINES.

The slight danger that firemen run through the electric current passing from heavily charged wires along the stream of water they are squirting is proved by an experiment conducted by Ugo Tartaglini and reported in *La Scienzu per Tutti*.

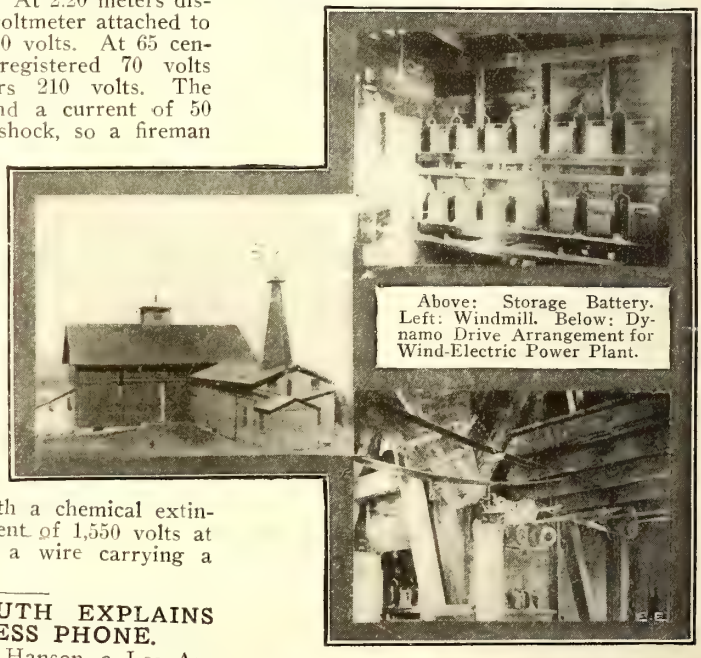
A trolley car wire charged with a direct current of 525 volts had one end grounded; on the other end he directed a stream from a hose with a nozzle 15 millimeters in diameter. At 2.20 meters distance a voltmeter attached to the nozzle registered 20 volts. At 65 centimeters distance it registered 70 volts and at 20 centimeters 210 volts. The average man can stand a current of 50 volts without serious shock, so a fireman who holds his nozzle 5 or 6 feet from a live wire runs no great danger.

Mr. Tartaglini made the same experiment on two lines of alternating current, one with 2,300, the other with 4,600 volts, and the voltmeter did not register any current in the stream of water, although a slight shock was perceptible when he put his hand into it. With a chemical extinguisher he got a current of 1,550 volts at 225 millimeters from a wire carrying a current of 2,050 volts.

CALIFORNIA YOUTH EXPLAINS NEW WIRELESS PHONE.

Earl C. Hanson, a Los Angeles youth, states that he has evolved a wireless telephone apparatus capable of operating between the shore and boats at sea. Young Hanson believes his system will render life saving in the future far easier than it has been heretofore.

Hanson has been working on his idea for years. He has applied for a patent, and those who have inspected his workshop pronounce his scheme feasible. For the benefit of the skeptics, the inventor recently gave a demonstration at the Venice pier, when he explained how his apparatus works.



Hanson, who began his work on the instrument when he was 12 years old, declares that the apparatus is inexpensive. A case two feet square will hold it. It can be operated like an ordinary telephone. The world has been a long time waiting for such a device.

WINDMILL GENERATES ELECTRICITY FOR HOUSE AND BARN.

By H. E. Zimmerman.

It looks as though the farmer, who has learned to appreciate the cheap power produced by the windmill, is going to extend its utility by inducing it to make electricity as well as to pump water. A Wisconsin farmer—J. F. Forrest, of Poynette, that State—has adopted a very unpretentious and practical method of carrying out this idea. To a 12-foot windmill on his farm he has harnessed a dynamo. This, in connection with a storage battery, converts and stores the energy of the wind into that of electricity. The amount thus rendered available is sufficient to light a system of 25 lamps distributed through the house and barn and to operate an electric flatiron and vacuum cleaner. Feed is also ground for the stock and conveyed to bins through a canvas conveyor.

The lighting system is a low-pressure, 30-volt affair, while the flatiron and vacuum cleaner are supplied from a separate 110-volt generator. The storage battery and generators are located in a shed, or wing of the barn, over which the windmill is erected. Specially designed generators and governor pulleys serve to stabilize the usual erratic speed of the windmill. An automatic cut-out in circuit between the generator and storage battery keeps the current in the latter from flowing back into the generator and reversing its polarity. With the electricity costing practically nothing after the equipment is fully installed, the owner's plan is to use it lavishly while the wind blows, and save it during the calm. Some day the windmill-electric plant may be so common that we no longer will look upon it as a curiosity.

Above: Storage Battery. Left: Windmill. Below: Dynamo Drive Arrangement for Wind-Electric Power Plant.

AS OF OLD.

Fond Mother—"Bobbie, come here. I have something awfully nice to tell you."

Bobbie (age six)—"Aw, I don't care. I know what it is. Big brother's home from college."

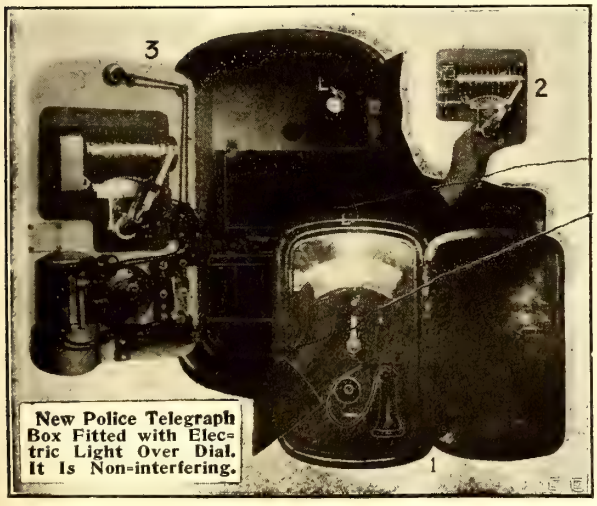
Fond Mother—"Why, Bobbie, how could you guess?"

Bobbie—"'Cause my wireless won't work no more!"

The carelessness of some people is astounding. A recent report has it that a baker stepped on a cinnamon bun and the "currant" ran up his spine!

AN IMPROVED POLICE TELEGRAPH BOX.

By Warren E. Fastnacht.



Police telegraph boxes are very often located in such a position that it is impossible for the officer to see the index dial at night, and unless he uses his electric pocket-light or a match he very often sends in the wrong report. In this improved box there is a light over the index dial, which is operated by the button in the end of the index lever; the officer pressing this button in the act of setting the lever to the proper code index, see Fig. 1. In other boxes use is made of illuminated dials of opalite glass, lighted from the rear. This opalite plate with black letters makes an efficient dial, both day and night.

In the smaller cities very often the boxes are placed far apart and, as the officers' beats overlap, a number of them report from the same box. The greatest number of signals which can be sent in from the boxes on the market at the present time is seven, and this does not meet the demand in many cities. Twelve different signals can be sent in from this new box and, as the code is made up of a number of round head screws properly spaced in holes on a revolving cylinder or drum (see Fig. 2), the code or the number of the box can be readily changed without removing the mechanism. In police reports each officer has a particular number or report at each box, and this number or report is always followed by the number of the box, so that the desk man knows exactly where the report comes from.

This set is non-interfering, as the moment the drum starts to revolve the index lever is locked and remains locked until it completes its function.

To protect the boxes and mechanism and also the officers from burn-outs or shocks, the inner boxes are wholly constructed of asbestos wood. The officers are further protected, aside from grounding the outside shells, by enclosing the entire receiver cord in a flexible rubber tube.

Very often there are repairs to be made after dark and it is not very satisfactory or handy for one man to use a flash-light or a lantern. In this box there is a small spot-light placed in an upper right corner of the inside chamber and mounted on a ball socket joint, which permits its being directed toward any part of the mechanism (see Fig. 3). This light as well as the one

New Police Telegraph Box Fitted with Electric Light Over Dial. It Is Non-interfering.

above the index dial are supplied from the local talking battery.

By the removal of only three screws, the whole of the signaling mechanism, including the index lever and starting lever, can be removed from the cabinet and taken in somewhere to be repaired. In removing this mechanism the index and starting levers pass through openings in the door of the inner chamber.

SUBSTITUTES FOR COPPER IN GERMANY.

So scarce has copper become in Germany, owing to the trying conditions of the war, that substitutes have been found to replace the copper wherever possible, especially in electrical plants, where, of course, such large amounts of this valuable metal are used. The new regulations of the German Association of Electrical Engineers cover this saving of copper by the substitution of other metals, notably zinc and iron.

Zinc busbars are advocated, and tables have been worked out for the carrying capacity of same, as well as for zinc bolts and zinc and iron wire. Where zinc is used its low mechanical strength, low elasticity, low melting point and its sensitiveness to high and low temperatures must be taken into account, of course. Wherever iron and steel are used for contacts they must be protected properly by means of zinc plating, lead plating, or else by greasing, etc.

With regard to iron busbars, the rule in the case of direct current for the permissible current is to have the relation of 1 to 2.8 to the permissible current in copper bars of the same dimensions. If the war continues copper will be nearly unknown in Germany.—*Elec. World.*

WIRELESS SERVICE DIRECT TO ARGENTINA.

Chauncey Eldridge, president of the Federal Holding Co., of New York City, which controls the Poulsen wireless telegraph patents in this country and has for three years operated a wireless system between San Francisco and Honolulu, announced recently that the company had obtained a concession from the Argentine Government for the erection of a high-power wireless station at Buenos Aires.

Mr. Eldridge said that it was intended to begin the building of stations with wireless towers 1,000 feet high near New York City and near Buenos Aires within a short time, and that probably within a year there would be for the first time direct communication between this country and South America by wireless.

The proposed wireless towers of 1,000 feet in height will be higher than any now in use, and the distance of 4,600 nautical miles between New York and Buenos Aires is a greater distance that any now spanned by ordinary radio stations. The longest wireless span at present in commercial operation is from Tuckerton, N. J., to Eilvese, Germany. The Tuckerton station uses the Poulsen wireless apparatus of less than 100-kilowatt capacity. The proposed plants will have a 300-kilowatt capacity.

AN ELECTRIC SIGN THAT DANCES.

One of the latest electric signs which interests thousands of persons nightly is seen herewith. We illustrate night view of the sign. The operation of this magnificent sign is indeed interesting as the mammoth figure, representing a Scotchman, continuously performs numerous steps of the "Highland Fling." This huge figure is 47 feet high and is mounted on a frame 50 x 50 feet. Upon the same frame the words "Haig and Haig" with the other words of the sign are mounted. The large letters are 12 feet high, while the others vary in size.

In this Latest New York Electric Sign the Highlander Dances Briskly, Attracting Great Crowds Nightly.

This sign employs about 2,000 incandescent electric lamps, which are controlled automatically by an ingenious flasher switch. This is another addition to the spectacular array of signs studding Broadway at 46th street, New York City, aptly called the "Great White Way." This unique display was built by O. J. Gude & Co.

OUR NAVAL RADIO SERVICE.

Our naval radio service now includes 47 land stations scattered all over the world. Two of these are high-power stations having a generating apparatus of 100 kilowatts or more. They are located at Darien on the Canal Zone and at Arlington, Va. A third station of the high-power type will be completed at San Diego within the next six months, while contracts have been let for two others—one in the Hawaiian Islands and one in the Philippines. These new stations are being constructed along the most modern lines. It is believed that they will have a much wider range of communication than any others in the world, and their completion will put the United States distinctly ahead of any other nation in radio equipment.

Why not improve your electrical education? Read *The Electrical Experimenter* every month.

The Tesla High Frequency Oscillator

By H. Winfield Secor, E.E.

TESLA, probably the highest authority in high frequency electrical engineering to-day, has not been dreaming these past few years, although we have not heard much from him, except through the daily newspapers, which now and then publish some world-startling interview describing a "marvelous" Tesla wave with which it is possible to communicate with Mars and several hundred other astounding stunts that the winner of the Noble physics prize probably never even thought of, much less attempted to accomplish.

Most of our readers have, no doubt, seen pictures of the famous Tesla wireless tower located at Shoreham, Long Island, and which structure has involved the expenditure of a vast sum of money. From this lofty structure, which was designed in the neighborhood of 20 years ago by Dr. Tesla and his associates, there was to be propagated an electric wave of such intensity that it could charge the earth to such an extent that the effect of the wave or charge could be felt in the utmost confines of the globe.

Our front cover illustration shows the Tesla tower in (theoretical) operation and, in line with some of the latest statements from this marvelous man, there may be perceived several dreadnoughts being blown to atoms, which is due to the high tension electric wave sent out from this center of vast electrical activity. Tesla, for obvious patent reasons, does not go into details just how whole fleets of a hostile navy can be destroyed in this way by means of powerful electric waves, but quite possibly he has in mind the fact that the latter can be tuned, undoubtedly, to a particular wave of certain frequency and power to accomplish this result when liberated from such a mighty station or oscillator as that located on Long Island. Such ships as the great steel shell dreadnoughts of to-day would, of course, have a large electrical capacity and this would help out the Tesla theory which covers the transmission and reception of an electric wave of sufficient intensity to do great good or damage, as the case might be.

The illustration on the front cover of this issue shows future possibilities which may be developed on the Tesla theory as a foundation. The location of the oscillator tower, from which the electrical energy is transmitted, and also the position of the war vessels being blown up are not to be considered literally in the way they are here shown. As a matter of fact, the enemy could soon shell the tower down.

Fig. 1. Probable Appearance of the Wonderful Tesla Oscillator Tower at Night—It Is Located at Shoreham, L. I., and Is Intended for Radiating Electrical Energy in the Form of High Frequency Waves Propagated Thru the Earth Itself—Tower Stands 185 Feet High.

and hence it becomes evident that if this system is ever perfected and applied practically, the elevated radio energy transmitting station will have to be placed at a considerable distance inland. Again, as this wireless energy can be transmitted hundreds and even thousands of miles without any appreciable loss, according to Tesla's beliefs and statements, no disadvantage or inefficiency would be incurred by so locating the tower away from the coast; but conjointly, on this theory, the invading fleet of war vessels could be destroyed when they were still several hundred miles off shore. Hence, it would be impossible for them to hurl projectiles this distance. Also presumably this method of detonating the powder magazines of the war vessels could be applied to similar containers of high explosives on land, such as those carried by the heavy artillery corps of an invading army.

Further, it may be said that Tesla, all in all, does not believe in the modern Hertzian wave theory of wireless transmission at all. Several other engineers of note have also gone on record as stating their belief to be in accordance with Dr. Tesla's. More wonderful still is the fact that this scientist promulgated his basic theory of *earth current* transmission a great many years ago in some of his patents and other publications. Briefly explained, the Tesla theory is that a wireless tower, such as that here illustrated and specially constructed to have a high capacity, acts as a huge electric condenser. This is charged by a suitable high frequency, high voltage apparatus and a current is discharged into the earth periodically and in the form of a high frequency alternating wave. The electric wave is then supposed to travel through the earth along its surface shell and in turn to manifest its presence at any point where there might be erected a similar high capacity tower to that above described.

A simple analogy to this action is the following: Take a hollow spherical chamber filled with a liquid, such as water; and then, at two diametrically opposite points, let us place, respectively, a small piston pump, such as a bicycle pump, and an indicator, such as a pressure gauge. Now, if we suck some of the water into the pump and force it back into the ball by pushing on the piston handle, this change in pressure will be indicated on the gauge secured to the opposite side of the sphere. In this way the Tesla earth currents are supposed to act.

The patents of Dr. Tesla are basically quite different from those of Marconi and others in the wireless telegraphic field. In the nature of things this would be expected to be the case, as Tesla believes and has designed apparatus intended for the *transmission of large amounts of electrical energy*, while the energy received in the transmission of intelligence wirelessly amounts to but a few millionths of an ampere in most cases by the time the current so transmitted has been picked up a thou-

sand miles away. In the Hertzian wave system, as it has been explained and believed in, the energy is transmitted with a very large loss to the receptor by electro-magnetic waves which pass out laterally from the transmitting wire into space. In Tesla's system the energy radiated is not used, but the current is led to earth and to an elevated terminal, while the energy is transmitted by a process of conduction. That is, the earth receives a large number of powerful high frequency electric shocks every second, and these act the same as the pump piston in the analogy just cited. These electrical impulses or shocks given to the earth are to be picked up at receiving stations by erecting a suitable capacity in the form of a metallic tower, as will be described more in detail hereafter.

Quoting from one of Tesla's early patents on this point: "It is to be noted that the phenomenon here involved in the transmission of electrical energy is one of *true conduction* and is not to be confounded with the phenomena of *electrical radiation* which have heretofore been observed, and which, from the very nature and mode of propagation, would render practically impossible the transmission of any appreciable amount of energy to such distances as are of practical importance."

He states further: "From my experiments and observations I conclude that with electromotive impulses not greatly exceeding 15,000,000 or 20,000,000 volts, the energy of many thousands of horse-power may be transmitted over vast distances, measured by many hundreds and even thousands of miles, with terminals not more than 30,000 to 35,000 feet above the level of the sea; and even this comparatively small elevation will be required chiefly for reasons of economy, and if desired it may be considerably reduced; since, by such means as have been described, practically any potential that is desired may be obtained and the currents through the air strata may be rendered very small, whereby the loss in the transmission may be reduced. It will be understood that the transmitting as well as the receiving coils, transformers, or other apparatus may be in some cases movable—as, for example, when they are carried by vessels floating in the air, or by ships at sea."

Tesla is not an idle dreamer, as many men are inclined to believe, but back in the year 1898 he succeeded, in some very elaborate tests carried out in Colorado, in producing high frequency electrical discharges, the like of which had never before been witnessed by man, nor have they been duplicated since, to our best knowledge. Some of these sparks measured 100 feet in length and produced a roar like the Niagara Falls. The multitude of mighty sparks and flashes produced a discharge so terrific that no human being could stay in the building in which they took place. Some of the sparks were as thick as a man's arm and others manifested even greater intensity. They were produced by a gigantic Tesla high frequency coil with which experimenters of to-day are more or less familiar in a small way. About 300 kilowatts were utilized in producing these discharges, which resembled actual lightning bolts and not imitation ones. The amperage measured 800 and the voltage was up in the millions. The illustration of these sparks, as well as Tesla's early work along this line, have been covered in previous issues of *The Electrical Experimenter*.

Regarding the Tesla tower on Long Island and the general engineering features of same, we may refer to his patent which covers the design of the high frequency apparatus of mastodonic design and capable of charging the structure at several million volts pressure. The external appearance of the Tesla generating plant and antenna support (185 feet high) are shown

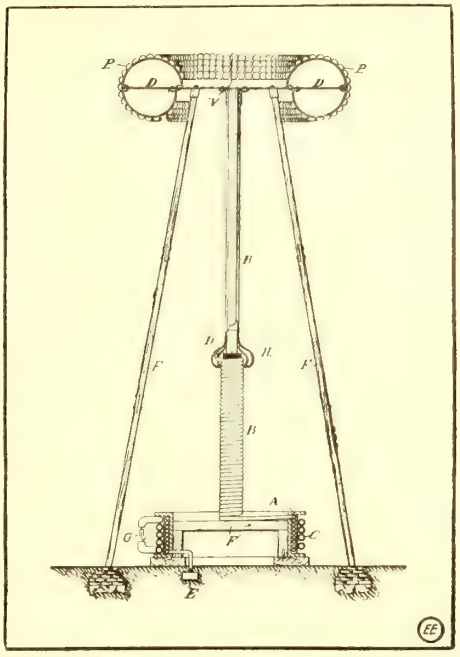


Fig. 2. Structure of the Tesla High Frequency Tower and Exciting Coils.

at Fig. 1. The huge high frequency step-up transformer is shown diagrammatically at Fig. 2.

Referring to this great structure which involves several peculiar design features, we see at the upper extremity a large capacity, D. This is made up of a metal framework upon which there is mounted a vast number of hemi-spherical metal electrodes. These are advocated for the reason that the minimum electrical leakage will then ensue. As points, of course, discharge any high tension current as rapidly as possible, they are done away with, as this is exactly what Tesla does not desire to have take place in this instance. The complete electrode comprises a suitably shaped metallic ring and the half-spherical electrodes appear at P P. Hence, within a reasonably small space an extremely large electrical capacity is formed. This capacity rests upon insulating supports, which in turn are well insulated from the earth.

The high frequency exciting circuit comprises a massive coil, A, which is in close inductive relation with the primary winding C, one end of which is connected to a ground plate, E. The other end of the coil is led through a separate self-induction and auto-transformer coil, B, and the metallic cylinder B^1 to the terminal D. At

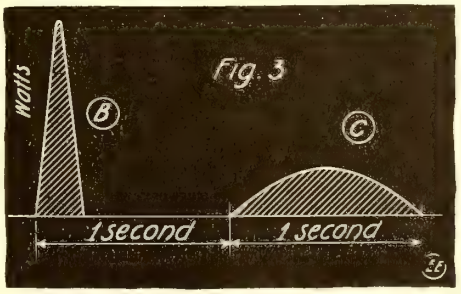

Fig. 3. Diagram Showing How the Rate at Which Energy Is Dissipated Increases as the Time Element Decreases.

the apex of the mast the connection with D is to be made at or near the center, Tesla specifies, in order to secure a symmetrical distribution of the current. Otherwise, when the frequency is very high and the flow of large volume, the performance of the apparatus might be impaired. The primary C is excited in any desired manner, from a suitable source of current G, which may be an alternator or condenser, the important requirement being that the resonant condition is established; that is to say, that the terminal D is charged to the maximum pressure developed in the circuit.

The adjustments should be made with particular care when the transmitter is one of great power, not only on account of economy, but also in order to avoid danger. It has been shown that it is practicable to produce in a resonating circuit as E A B B D immense electrical activities, measured by *tens and even hundreds of thousands of horsepower*, and in such a case, if the points of maximum pressure should be shifted below the terminal D, along coil B, *a ball of fire* might break out and destroy the support F or anything else in the way. An induced earth current out of phase with a "tower capacity" current meeting at any point along the coil, etc., would buck each other and so balls of fire could be produced; the instantaneous value of the energy so involved being truly astonishing. For the better appreciation of the nature of this danger it should be stated that the destructive action may take place with inconceivable violence. This will cease to be surprising when it is borne in mind that the entire energy accumulated in the excited circuit (instead of requiring, as under normal working conditions, one-quarter of the period or more for its transformation from static to kinetic form) may spend itself in an incomparably smaller interval of time, *at a rate of many millions of horsepower*. The accident is likely to occur when, the transmitting circuit being strongly excited, the impressed oscillations upon it are caused, in any manner more or less sudden, to be more rapid than the free oscillations.

It may seem quite impossible for many of our readers to comprehend the large figures cited by Tesla with regard to the voltage and horsepower liberated or propagated from such a structure as he has designed. However, by referring to Fig. 3, this matter can be more readily understood. This diagram shows how a graphic curve, C, would appear for, say, 100 horsepower liberated or passing through a circuit for the time period of one second. Now consider that instead of this 100 horsepower of energy being allowed to pass along in normal fashion for a period of one second, that it is heaped up or liberated in about one-fifth of a second as at B. The horsepower or watts, let us say in this case, would be dissipated at a much higher intensity rate than was the case at C. In other words, the rate of dissipation in this instance would be 500 horsepower for one-fifth of a second instead of 100 horsepower for one second.

Now consider that a Tesla current as produced by an oscillatory discharge from condensers and the like take place in very small fraction of time, then Tesla's statements in his patent and aforementioned with regard to the production of hundreds of thousands of horsepower is not so fallacious at it may seem. In an interview with one of our editorial staff he has vouchsafed the information that the oscillator here pictured is supposed to be excited with an input of 300 kilowatts. The average person then begins to gasp for air. An input of only 300 kilowatts! How, then, could this tower be caused to oscillate and liberate energy at the rate of hundreds of

(*Continued on page* 663.)

Electricity Wonderful Aid to Modern Surgery

THERE have been various improvements made in surgical instruments in the past few years, and the apparatus described here is the final result of extensive experiments and painstaking labor on the part of specialists to evolve a device that would simplify operations on bones.

Heretofore an operation which necessitated the sawing or cutting of bones was more or less clumsily done, due to the fact that the instruments entirely suitable for this purpose were not to be had and the surgeon did the best he could with those at hand.

The surgeon of to-day, however, is equipped with a unique instrument for this work in the way of an electrically operated bone set, which is shown in Figs. 1 and 2. The outfit comprises a source of power, in this case taking the form of an electric motor made of very light material, a foot switch for controlling the motor and various attachments as shown in the illustration. They consist of a selection of various small drills, saws and cutters, and are all interchangeable. They are held in place by an automatic catch built in the motor shaft. A specially made angular twin saw is provided with this outfit and is used for very deep wounds.

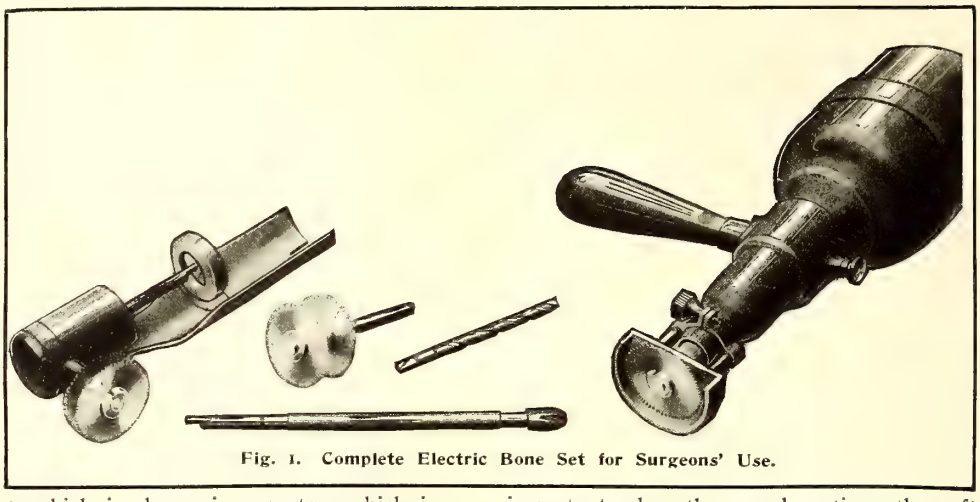

Fig. 1. Complete Electric Bone Set for Surgeons' Use.

The fact that these attachments can be so rapidly changed is of great value to the surgeon, as he can change from one to another almost as quickly as he could select an instrument from the table. Time is an important factor in any operation, as the faster the work is done the less danger there is of fatal results. Besides being very light and comfortable to handle, the motor used is very powerful. The apparatus as a whole is easily sterilized and thus reduces the liability of infection to a minimum.

The motor being specially designed for this work has several refinements not found in other small motors of a similar type. The most noticeable of these improvements is the way in which the flexible cable is connected to the apparatus. Formerly this flexible cable has been of more or less trouble, due to the fact that it often became heated and stalled the motor. In this design such trouble is done away with entirely.

The current to the motor is run through the foot switch previously mentioned and, as the name indicates, the latter is operated by the pressure of the foot. With this type of switch the surgeon had at all times perfect control over the speed of the motor, which is very important when the different attachments are being used.

With this bone cutting instrument bone grafts and their recipient beds can be speedily and accurately made with a minimum expenditure of time and work, with the consequent lessening of the danger from infection which contributes to the ultimate success of the operation.

Of the utmost importance to modern surgery is the method of administering the anaesthetic. In days gone by, when the surgeon was compared more or less to a "butcher," the usual manner of anaesthetizing the patient was to place a piece of cotton over his nose and mouth and then pour the anaesthetic, chloroform or ether, over the cotton. The vapor therefrom was, of course, inhaled by the patient with the desired results.

This method was improved upon by the use of a mask which was placed over the face. It had a receptable at the top in which gauze or cotton was placed. The liquid was poured on and the vapor, of course, inhaled with resulting unconsciousness.

There were drawbacks even to this method, and physicians started experimenting with apparatus that would simplify this part of the operation. Several schemes were worked out, but none possessed the great efficiency or ease of manipulation of the appliance illustrated in Fig. 3. This apparatus consists of four units: 1. A motor blower and rheostat. 2. Ether or chloroform container. 3. Mercurial manometer registering from 5 to 50 mms. and capable of being easily set for any operation and acting thereafter automatically. 4. Hot water for adding both heat and moisture to the vapor. Another form of an etherizing machine is depicted in Fig. 4.

The apparatus shown at the right is used for administering the gas to the patient. The mask is adjusted over the face, and the amount of ether to be given is placed in the vaporizing chamber. As soon as the heat is applied the ether is quickly vaporized and forced into the patient's lungs by means of the blower.

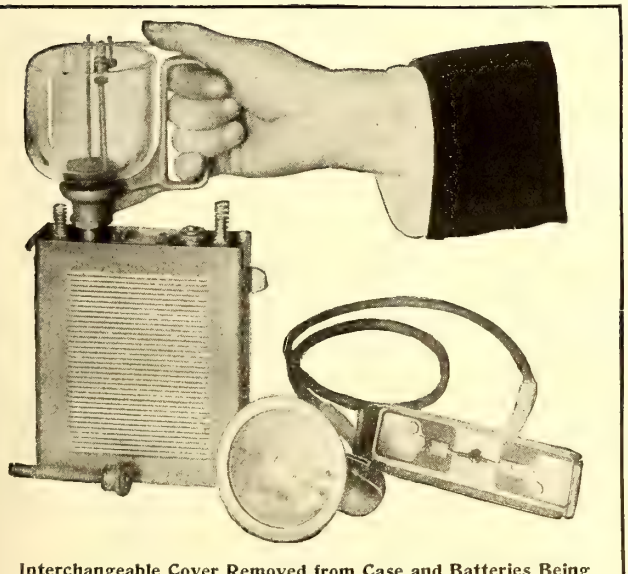
GREAT FUTURE FOR X-RAY.

The results already achieved by the X-ray in combating ills are only a hint of ultimate successes expected, specialists recently told the annual convention of the American Roentgen Ray Association. Dr. W. D. Coolidge, of Schenectady, N. Y., said that the investigators were dealing with the future and not so much with present attainments, because they saw tremendous discoveries clearly ahead within striking distance.

He spoke of the need of standardization and checks upon manufacturers of the apparatus used, and asserted the belief that it will be as simple a matter to standardize the equipment of X-ray specialists as it was the incandescent lamp. Experiments had shown, he said, that it was possible to get one-third more radiating energy with the direct current than from the alternating current and to vastly increase the intensity of the ray with the aid of revolving targets.

Edison Perfects Storage Battery Miners' Lamp



The latest device brought out by the Edison laboratory is a highly perfected storage battery miners' lamp. This is developed to the finest detail, and it has been considered so meritorious that it was awarded the Rathenau Medal of the American Museum of Safety. This medal is placed at the disposal of the above-mentioned museum by the Allgemeine Elektrizitäts Gesellschaft, of Berlin, to be awarded for the best device or process in the electrical industry for safeguarding industrial life and health. The Edison mine lamp was the first to receive this marked honor.

New Edison Battery Miners' Lamp in Use. The Angle of Illumination Is Well in Excess of the 130 Degrees Required by the Government.

The illustration herewith shows respectively the perfected Edison mine lamp in actual use down in a coal mine and the thumb actuated refilling device which is not only a great time and labor saver, but is also very cleanly in its action, preventing the spilling of the solution over the outside of the battery casing, etc.

The battery container holds two cells of the nickel-iron-alkaline type, and thus produces two and one-half volts. The elements, nickel hydroxide and iron oxide in a potash solution, are encompassed by a strong, nickel-plated steel container, hermetically sealed except at one small outlet for the escape of the harmless and odorless gases when being charged. The cell may be turned upside down without in any way proving disastrous to the miner or to the action of the battery. This is arranged for by the unique design of the ventilating tube, which prevents the escape of any of the solution, even though the cell be violently shaken. The cell fits snugly into a light outer casing, which is rust-proof and made of monel metal. The battery is held on the miner's back or, rather, at his waist line by means of a leather strap passed around the body. An extra heavy flexible conductor leads up to the lamp, which is fastened on to the cap. The lamp is usually lighted when handed to the miner and they are generally charged in groups every night at a central charging room or station located at the mouth or the entrance to the mine. The battery case is secured by a padlock so that it cannot be tampered with. The whole outfit proves practically foolproof and as safe as any lamp available for the purpose.

Interchangeable Cover Removed from Case and Batteries Being Watered by Automatic Filler.

The automatic battery filler and "watering" gauge shown in the second illustration makes it possible for unskilled attendants to readily care for the batteries. It assures absolutely proper filling in every case when employed, as it not only indicates when the normal level of the battery has been reached, but it also automatically cuts off the flow of water at that point. It can likewise be used for renewing the alkaline solution.

NEW HIGH-CANDLEPOWER FLASHLIGHT.

A novel and useful flashlight has been perfected by George K. Burleigh, known as the Fire Fly Light. It has many new features as well as being very attractive. The case (Fig 1), which contains an ordinary dry battery, is enameled red, the fiber disc which covers the battery white, the handle blue. The two tungsten lamps are operated from one switch, and by mirror reflection triple the illumination given by any single battery light is obtained. It gives a diffused and not a concentrated light, so that by placing it in one corner of a small room you can read in any part of the room. Other new features are that if anything happens to one of the lamps you always have the other in use, and the U clip shown in the cut, which slides up between battery and battery case, can be screwed to the floor of automobile or carriage, in any safe place, and the light can be pulled off the clip instantly to measure gasoline, read signboards, make repairs around motor, et cetera.

Fig. 1. New Double Bulb Electric Lantern.

The second illustration shows the strap furnished with each light for hanging it around the neck, with battery buttoned inside the coat. This gives at all times the free use of both hands. In this way it is especially useful in looking after the furnace, for the farmer pitching down hay or milking cows, firemen rushing from one room to another and carrying occupants overcome by smoke, etc. The whole outfit weighs about four pounds.

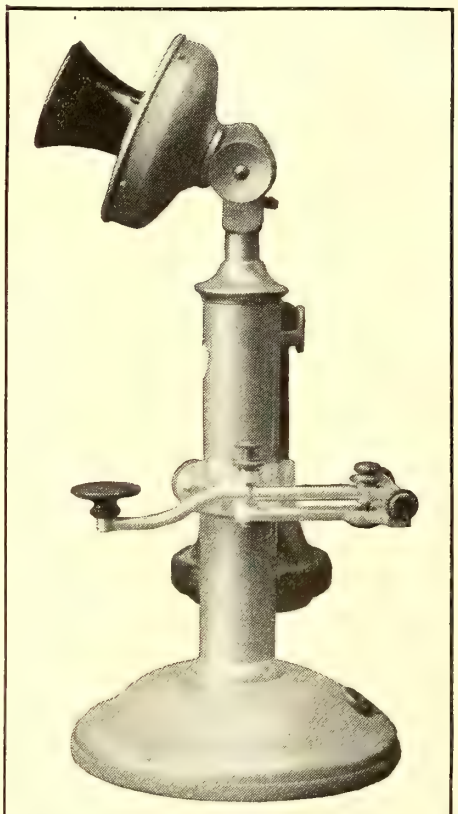
Fig. 2. Triple Bulb Battery Lamp Strapped Around Neck. Excellent for Firemen and Others.

UNIQUE DIVING BELL TO HELP RAISE SUNKEN SHIPS.

A California inventor has perfected a submerging or diving bell formed of a single hollow steel casting, which is capable of accommodating an operator, and it is

A large Diving Bell Designed to Aid in Raising Sunken Vessels.

provided with powerful securing or retaining magnets, as well as electric searchlights and large glass windows, through which the submerged wreck may be inspected This salvage machine, if so it may be termed, is suspended on a steel cable from a tender ship on the surface, as our illustration shows. When the steel shell attains the proper position with respect to the sunken vessel, the electric current flowing through an insulated cable from the tender on the surface is thrown into the powerful electromagnets and the entire ball is held rigidly at that particular point against the hull of the vessel. A specially devised and controlled drill then bores a hole in the steel shell of the sunken ship and by an ingenious arrangement of screws on the outside of the salvage machine, the body proper of same can be moved several feet laterally or vertically, with respect to the holding magnets. After a hole is drilled, this permits the operator within the bell to manipulate a magnetized arm, which picks up one of the pontoon cables, as may be noted in the illustration. The end of this cable is fitted with an automatically locking toggle hook which is secured in the hole previously drilled. Thus the operation is repeated until all the pontoon cables are fastened to the hull of the boat.



These pontoons are fitted individually with electric motor-driven pumps, so that the water can be pumped out of same separately or all together simultaneously; in this way the vessel is supposed to be readily raised to the surface, when it can be towed to the nearest harbor or to shoal water for overhauling and repairs.

Such work as this is extremely interesting to a large class of people, as many of the stories of sunken vessels carrying vast amounts of gold are not mythological, but actual facts, and a great number of these wrecks, worth many millions of dollars, are definitely charted on the hydrographic maps of the Government. To reclaim such wrecks and the buried treasure thus lost has been the dream of untold numbers of inventors, and this device bids fair to accomplish some valuable work in this direction.

TELEGRAPHING OVER TELEPHONE LINES WITH SIMPLE DEVICE NOW POSSIBLE.

A patent has just been allowed to Paul P. Banholzer, of Philadelphia, Pa., on a mechanical telegraph instrument for telegraphing by wireless telephone and over telephone circuits. It is claimed that this instrument will further introduce the dot and dash system of telegraphy, which can be understood by any wire operator. Furthermore, the sound it produces is unmistakable and carries much farther than the voice.

For telegraphing over telephone lines the modified key here illustrated is clamped to the post of a desk telephone and when the key is manipulated the Morse code characters are received at the distant end of the circuit clearly and distinctly. The dots and dashes on the key are transmitted

Simple Key Attachment Enables You to Telegraph Over Any Telephone Line

mechanically to the diaphragm of the microphone through the metal stand parts and are transmitted over the line, as are voice currents, and reconverted into sound waves in the receiver at the other end. A desk telephone, with this device attached, can be "jacked" into any telephone circuit and used as an extension telephone. In this way the hinged fastener can be used anywhere without having to change the fastener or use bushings.

This instrument is stated to be an especially useful device in connection with telephone train dispatching, since the telegraph system could be used when telephone conversation is not understood or is otherwise difficult owing to bad weather effects on the line, etc.

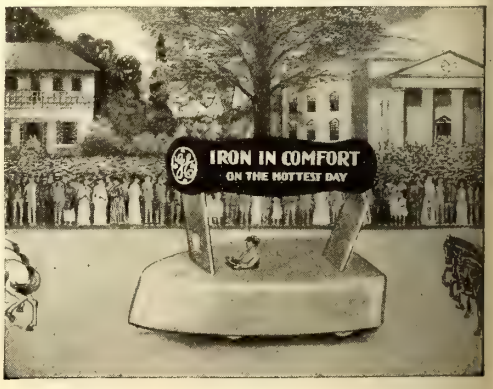
It is claimed that this key could be used with advantage in branch telegraph offices where there is but one telegraph wire. Such offices, as a rule, have a telephone, and this circuit could be used to forward their messages without having to wait their turn on the telegraph circuit.

Quite a number of these instruments are in successful operation in the South and West, and reports indicate that they now form a part of the permanent equipment of those lines.

There can be no induction on parallel lines, as no additional battery is required to operate the instrument. What has been said in regard to the wire telephone system also applies to the wireless telephone system.

CARNEGIE SENT FIRST TECH. WIRELESS MESSAGE.

Andrew Carnegie sent the first message from the new wireless station at the Carnegie Institute of Technology, Pittsburgh, Pa., the most powerful in the State, and one of the largest in the country, when he attended Carnegie Day celebration, Nov. 23. The outfit is nearly twice as strong as the average outfit on United States battleships, and will send messages as far as Colon, Panama.



The Radio Club of 30 members installed the apparatus. The club is composed of Tech. students and wireless men of Pittsburgh. It has applied for membership in the American Institute of Radio Engineers.

ELECTRIC IRON MAKES INTERESTING PARADE FLOAT.

In line with the widely extended advertising campaign during "Electrical Prosperity Week" there were many parades and electrical demonstrations conceived and carried out to further the aims of this business-getting propaganda.

Among the very interesting floats and beautifully decorated autos that appeared in the various parades there was one that seemed to appeal to the public more than the rest. This resembled a gigantic sad-iron mounted on an automobile. The illustration herewith gives some idea of the appearance of this unique float. In one of these recent events held at Liberty, N. Y., the sad-iron float was selected as one of the best decorated of all the entries made.

Such decorated autos or wagons do not cost an exorbitant amount, and the one just referred to entailed an outlay of about $31. This is very low when the size of the float is considered, the over-all dimensions of the outfit having been 16½ feet long, 7 feet wide, and 9½ feet high. Muslin was used to make a smooth outline of the base of the sad-iron, being stretched over an under

A Flatiron Float that Can be Built for $31 or Less.

framework or skeleton made up of some light wooden strips. Storage batteries and low-voltage tungsten lamps enable some wonderful, and spectacular effects of this nature to be attained at a nominal cost.

Electricity the Beneficent

By Benjamin G. Lamme

Cffief Engineer Westinghouse Electric & Mfg. Company, and Member Civilian Naval Advisory Board*

IMAGINE, if you can, that when you awake to-morrow morning, the whole world will be suddenly without electricity in any of its present forms. Have you even a faint idea how it would affect your every-day life? What would happen if such a cataclysm should take place over night? How would it affect humanity? This is the theme of the present article selected by its distinguished author. It makes good reading and brings home to us the fact that the world in its present state is vitally dependent upon the mysterious fluid.

THE benefits of electricity to mankind are so various and so far-reaching that it is difficult for any one person to fully appreciate them. These benefits are both direct and indirect, the latter sometimes far overshadowing the former. Many of the present generation are so accustomed to electrical appliances and methods that they do not fully perceive the large part such take in our daily life. It has been said that one cannot fully appreciate a thing until he has to do without it. This points to a very effective way of calling attention to the far-reaching influences of electricity in the life of the world.

Let us assume that by some means, all electrical apparatus, methods and usages are suddenly withdrawn from the world. By considering the consequences of this we can possibly get a fair idea of the scope of the electrical field.

Let us consider first the general subject of transportation. Possibly no other activity has had as great a bearing on the present high development of mankind as our modern methods of transportation. Taking steam operation, wherein does electricity play an important or controlling part? Or, by a more specific question, supposing the electric telegraph were suddenly eliminated, how would general railway transportation conditions be affected? They would be completely disorganized temporarily, and would be very greatly handicapped permanently. Rarely is it appreciated to what an extent our great railway systems are conditioned upon means for almost instantaneous communication between distant points. Without such means a busy railroad could only operate upon an exact time schedule. Once that schedule is broken, disorganization and disaster would follow. Incidentally, someone will suggest that if the electric telegraph were eliminated, the railroads would turn to the telephone. But this again is an electrical apparatus.

A second great item in railroad transportation at the present time is electric signaling for the dispatch and control of trains. If eliminated, this would certainly mean a great step backward, especially in sections of very heavy and frequent railway service.

What would be the effect of complete cessation of electrical operation of city, suburban and interurban cars? In the cities we might go back to horse cars for the surface lines. The service would be almost unbearable, but might be possible. Elevated trains in large cities could go back to steam, however, with great objections from adjoining business firms and residents. But subways—here would be a real nut to crack.

In suburban service, the elimination of the electric car service would spell disaster, except to those relatively few individuals who could have their own equipages. How few appreciate that the rapid growth of suburban districts has been consequent upon electric railways. Autobusses and "jitneys," or some other form of gasoline engine equipment, might furnish a solution eventually, but then, how about the electric spark for ignition?

Again, let us consider interurban car service. No other means can faintly compare with the electric car systems in bringing the people of city and country together. Steam service, with its infrequent trains, did little in this direction. The figures giving the great growth of passenger traffic between country and city districts following electric car operation, tell a most interesting story.

Electric haulage in coal mines is now standard practice. Decrease in fire risks and increased capacity are two prime reasons which have led to electric operation. Eliminate the electric current and coal mining can doubtless be carried on with more or less success, but with decreased production and increased cost, which must be borne by the public. We can always go back to the old ways of doing things, but we will have to pay the price.

In water transportation electricity, perhaps, has not played such a conspicuous part as on land. Yet if the electric installations on ocean vessels were eliminated, there would have to be quite a reorganization. Electric propulsion of large and high-powered vessels promises to be one of the most important steps in naval engineering in the near future. Wireless telegraphy has become a necessity in modern sea service.

Taking up next our business and industrial life, let us imagine a few of the things which would happen if electricity were entirely eliminated. Without the telegraph, business would be very badly handicapped, although it might limp along after a fashion. But the telephone—here would be the rub, if we had to give it up. Whole systems of conducting business are dependent upon the telephone. Disorganization would be certain to follow in many lines if it were eliminated. Even home-life would be greatly affected.

Let us next consider the elevator. What has been its influences on life and business in the cities? How about the large many-storied department stores? Can anyone conceive of a practicable 20 or 30-story skyscraper without elevators? And one must remember that most of these elevators are electrically operated. True, there are other very good methods of operating them, but nevertheless, the elimination of the electric elevator would make a large gap in our methods of vertical transportation.

This leads us to a very common piece of apparatus, namely, the electric motor. This has come into use so gradually, and with so little ostentation, that we almost feel that it has always been with us. Yet, in less than one generation, it has revolutionized all kinds of manufacturing establishments and industries. Take the electric crane for instance, what would the great industrial works of the present time do without this particular application of the electric motor? Take the use of electric motors in general throughout such establishments. How would the necessary power be distributed over the vast areas of modern manufacturing plants if electricity were eliminated? Possibly a way could be found, but in most cases it would require a complete reorganization of many of our present industrial methods, and efficiency would take a long step backwards.

In the smaller shops and power applications, the electric motor fills a fully as important place. Small steam plants are utterly impracticable in some places. Gas or gasoline engines are often very objectionable, but still possible. But how about the electric spark for ignition, if electricity is to be eliminated? It must also be kept in mind that many establishments using power have been so designed that the replacement of the electric motor by any form of steam or gas engine is not practicable for many reasons outside the mere question of ability of the latter to develop the required power. Available space, high temperatures, fire risks, disposal of burnt gases, noise, and many other conditions enter into this matter.

Outside of shops and industrial plants, the electric motor also has a very wide field of application, and many kinds of service have developed simply through the availability of the electric motor as a source of power. This part of the subject is too large to allow consideration in detail in any article of limited scope.

Coming now to one of the oldest and best known fields of electric activity, namely, electric lighting, we find a class of service the abolishment of which would be felt by all classes in civic life. If electric street lighting were abandoned, we could doubtless manage with some other form of illumination, but the results probably could never approach the present standard. In the case of interior lighting, the result of a replacement of the incandescent lamp by other forms of illumination would create still more dissatisfaction than in the case of street lighting. It may be said that the vast majority of electric light users would pay a greatly increased price rather than be obliged to give it up in favor of any other known method of illumination.

Another class of electric service of a comparatively recent period is represented by household utilities, such as electric irons, toasters, coffee percolators, and other electric heating appliances. Motors for general household purposes, for running sewing machines, washing machines, etc., are becoming rather common. These are luxuries which are fast becoming necessities. If these were eliminated a big gap would be created, even though they represent a comparatively new field of application.

The above is only a very incomplete presentation of the direct possibilities which would occur in case there was a complete cessation of all electrical activities. Many of the special applications of electricity such as electro-chemical, electro-metallurgy, electro-fusion, etc., have not even been touched upon, and yet great industries have been built upon them. The

GEORGE SIMON OHM.
MARCH, 1916, MARKS HIS 128TH BIRTHDAY.

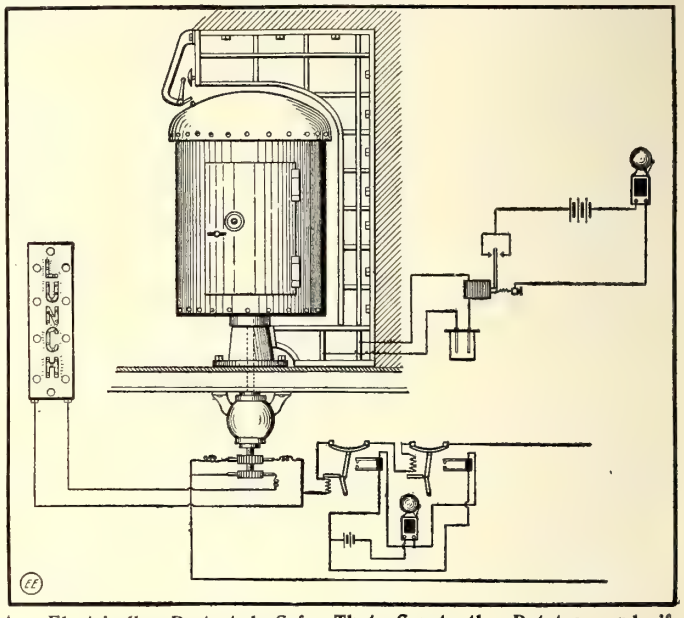
(Born 1787—Died 1854.)

In 1827 Dr. George Simon Ohm, a German physicist, rendered a great service to electric science by his pamphlet containing his theories that the flow of electricity was governed by certain fixed laws. It explained what is accepted and known to-day as "Ohm's Law," and the "Ohm" is now universally employed as the unit of resistance in an electrical circuit. This law states that *The current varies directly as the electro-motive-force, and inversely as the resistance of the circuit.* Like all great inventors, Ohm was ahead of his time, so his ideas were ridiculed by great and small.

He was the son of a thrifty locksmith, of keen intelligence, and was born March 16, 1787. George Simon Ohm started his career in the village of Erlangen, Bavaria, as a helper in his father's shop. He inherited a love of mathematics from his father, a man of studious disposition. The parents early recognizing the latent talent in their son, accumulated enough money to send George to college. Owing to lack of funds, he was compelled to forego his schooling a few years later. He then reluctantly turned to teaching in a primary school.

George Simon Ohm, After Whom the "Ohm," Unit of Resistance, is Named.

This sudden financial stress did not daunt the young locksmith student one bit. He filled in most of his spare moments studying, but it must not be thought that he gave up all outdoor pleasures. Unlike Ampère, he was popular among the students and professors and joined in all the social life and athletic games.



In 1817 George Simon Ohm was appointed professor of mathematics in the Jesuit Gymnasium at Cologne. The following year he published his famous "Elements of Geometry." He resigned a few years later and went to Berlin, where he became interested in electrical experiments. Ohm then pushed his researches in the footsteps of Galvani and Volta, the results of which were embodied in a pamphlet called "The Galvanic Circuit."

About 14 years after publishing his theories, when he was in the midst of his wonderful career, Ohm was awarded the Copley medal by the British Royal Society in 1841. For a time thereafter professional jealousy reduced Ohm to a condition of comparative poverty, but regardless of this he continued the course of his investigations. The International Congress of 1881 gave Ohm's name to the unit of electrical resistance, and so his name came to be one known to all electricians in every part of the globe. Wherever you find the volt chasing the ampere around the circuit, there also will you encounter the "ohm," who bucks their onward rush with all the strength he possesses. Ohm's law written algebraically, $C = \frac{E}{R}$, ($C = \frac{E}{R}$), has been adopted as the emblem of the National Electric Light Association, one of the most powerful scientific organizations extant to-day.

Electricity Renders Safe Impregnable.

By George C. Denny.

Electricity, the adroit crook's most formidable enemy, is forever beating him at his own game. It moves silently and quickly, strikes when least expected and, landing him behind the bars, prevents him from obtaining his much-desired haul. In a revolving safe, the subject of a recent patent, which appears to be the latest invention for foiling the expert cracksman, the unknown medium plays the leading role. By continuously turning the safe, which may be made still more impenetrable and secure by placing it in an enveloping sheath, electricity will render his drills and other tools of this class ineffective against it and, moreover, prevent the use of an explosive as by pouring it in the cracks in the safe or in a hole bored for that purpose, as is usually done. The motion of the safe and sheath, too, will attach to it so many uncertainties that the ambitious yeggman who might smilingly tackle the job, were the safe at a standstill, would soon turn away for an easier one with less risk.

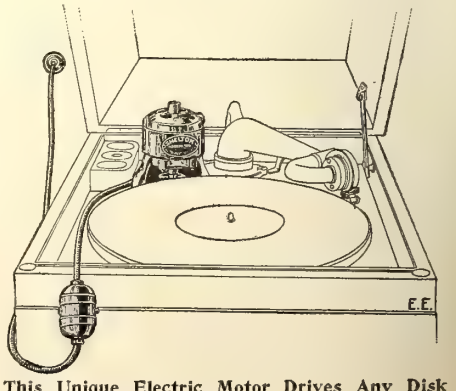
An Electrically Protected Safe That Constantly Rotates, and if Tampered with Gives a Code Signal on the Sign Outside the Building.

That the motion of the safe may not be slowed down or stopped, over-load and under-load cut-outs are provided which are acted upon by the motor which turns the safe and which runs at a regular and predetermined speed. When one of these cut-outs is placed in action by an over- or under-load on the motor, a signal is promptly given that the safe is being tampered with.

To indicate the position of the safe door a bell mounted in a certain place on the sheath is struck, or a light placed in the proper position energized when the door has made a complete turn. These devices become necessary when the safe is placed in a niche in the wall or surrounded by a lattice work, as shown in the illustration. This manner of placing the safe effectively prevents its motions from being followed and the safe or sheath from being worked upon. The lattice work is also wired, so that any tampering with this structure would cause the sounding of an alarm.

A street sign with a number of lights, secretly wired to the safe and placed outside, would, by the alternate lighting of the lamps, caused by a commutator on the motor shaft, inform a watchman that the safe was intact at the completion of each revolution. Another novel method of protection would be to place the safe in a window, and the revolving thereof, besides attracting attention and acting as an advertisement, would insure the safety of its contents.

CLASSIFIED!



The applicant for the post of second wireless operator seemed somewhat dense, but otherwise appeared to be a clean-cut chap.

"I suppose you are a single man?" asked the port operator during the conversation.

"Er—er, no, sir," he stammered; "I'm twins."

A MOTOR THAT OPERATES ANY DISK PHONOGRAPH.

One of the latest electrical motor productions brought out by a New York concern appears to solve a very important problem which has long confronted the owners of a Victrola or other disk-type talking machine. This motor, which sells at a nominal price, does not have to be attached or screwed fast to the cabinet of the talking machine in any way, but simply rests on the shelf of same. On the lower end of the motor shaft is secured a friction pulley, which by frictional contact with the disk platen of the phonograph drives it at the proper speed. The regulator on the talking machine can be employed in the usual way for varying the speed of the record.

This Unique Electric Motor Drives Any Disk Style Talking Machine. Does Not Mar the Cabinet.

RADIO AMATEURS TO RELAY MESSAGE OVER U. S. ON FEB. 21.

Another radio M. S. G. (message) will be relayed from Rock Island Arsenal, Illinois, on Feb. 21. This radiogram will be delivered to 9 X.E. by the U. S. Army officer in charge of the arsenal station.

Owing to the fact that Feb. 22 is Washington's Birthday the message will be partly military in nature and also in keeping with the spirit of the day, which is dear to the heart of every loyal American.

It will be sent out on a Q. S. T. by many stations—special and amateur. It will be up to the many stations listening in to pick up the M. S. G., as the list of sending stations, their time and wave length will be given in the final instructions.

Each Governor and Mayor of every State throughout the United States will receive this message. Arrangements have been completed with the Boy Scouts of America to assist in delivering it wherever possible, and suitable ceremonies will be held at Bunker Hill and Mt. Vernon by these coming citizens of the U. S. A.

Valuable assistance has already been given by the various local and national radio clubs. The A. R. R. L. have promised their assistance. Every wireless amateur in the country is requested to "talk" this over with his favorite relay station. Telegram blanks will be furnished each receiving station later by 9 X.E.

N. A. A. (Arlington) has promised to assist in this great undertaking, the same as it did during the Rotary relay message sent broadcast on Dec. 31 last, by sending out a warning to all amateurs to "keep out," after the N. A. A. routine report of Feb. 21, 1916.

We all owe our thanks to Capt. Bullard, who has given us every assistance. All are requested who may be assigned the delivery of this message in their respective States or cities to deliver it, no matter where your man may be. Yours is a perfectly legitimate mission and you have no cause to fear anyone—just land your man and give him the telegram.

Yours for a great success, 9 X.E.

[*The Rotary M. S. G. of Dec.* 31, 1915, *was received in Texas and Utah. All States between these received the radiogram. Also Niagara Falls to Washington, D. C., and all cities between received it.*]

UNIQUE ELECTRICALLY LIGHTED TRAFFIC SIGNS.

The accompanying illustration depicts

Mt. Vernon, O., Makes Use of Portable, Electric-Lighted Traffic Signs.

the unique and also inexpensive form of electrically lighted traffic signs which have been erected at the four entrances to the public square of Mt. Vernon, Ohio. As noted from the illustration, these signs read, "Keep to Right." These words are visible to traffic in either direction, both night and day. At night there are two 25-watt tungsten lamps suspended from brackets above the sign on either side of same, so that it can be read at a considerable distance.

The upright standards supporting the sign and tungsten lamps are constructed from 1-inch conduit. Above the lamps there extends a 10-foot piece of ¾-inch conduit, through which the feed wires for the lamps are run. These wires are connected with the over-head 110-volt circuit.

Prior to the erection of these signs, which, by the way, may be moved about, it was necessary to keep two or three policemen on duty at the center of the intersections in order to prevent collisions.

President Wilson 'Phones Message to Boys' Club

The Boys' Club, located in New York City at Avenue A and Tenth street, had what might be called, without a doubt, a "large size" evening on Jan. 17 last, when over 200 newsboys who were campaigning for a half-million-dollar fund for the erection of clubhouses listened to a talk by President Woodrow Wilson in the White House at Washington through the medium of a long-distance telephone and a number of multiple receivers.

Photo Copyright by International Film Service.

At the Boys' Club, New York City, When President Wilson Talked to Them Over the 'Phone from Washington.

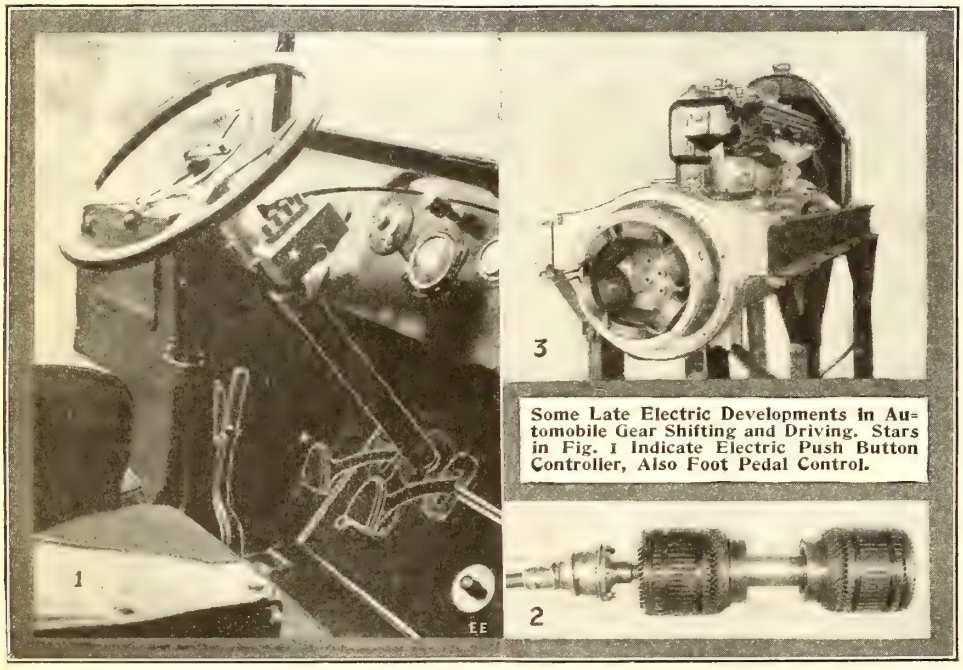
The boys were so delighted by the President's words of encouragement that they cheered him to an echo over the 'phone, and he was highly pleased by this ovation. The lads who heard the President had been invited by the club from the streets of the East Side of New York; many of them were newsboys with hands blue from the cold, with torn clothing and heavy, ill-fitting shoes. They were gathered behind desks arranged in a large square in their gymnasium, their begrimed faces glowing with the enthusiasm of the moment, their hearts beating furiously as they listened for the first words of the President's talk. All of these boys are to be beneficiaries of the campaign carried on to raise the sum of $500,000 for new clubhouses in Greater New York.

This was the President's address: "I am very glad to have this opportunity to address a few words to the boys. I hope with all my heart that you will have success in raising this fund to be devoted to the youth of America. I hope this may be only the first of the signs of friendship that all ought to feel for the boys who bring us our papers. My sympathy has always been with the newsboys. Please give them all my very best wishes."

Behind the boys who held the receivers were several hundred other members of the club. The smallest lads were given the preference at the receivers, but while the President spoke many receivers were passed back into the crowd to give others an opportunity to hear. The doors of the clubhouse were closed and locked at 8 o'clock. Outside the street was black with youngsters who could not gain entrance. They took the cheering up after the President had talked and for several minutes Avenue A was filled with lusty shouts, the like of which had not been heard in that locality in many a day.

Long live the telephone, the annihilator of distance and the gift of science to mankind which has made it possible for gatherings such as this to hear and enjoy a speech by such men as President Wilson, although they may be located hundreds or even thousands of miles away. It is now a common occurrence for club diners in New York to listen to speeches made in San Francisco, and vice versa. For these occasions special equipment is installed by the local telephone company, including a sufficient number of multiple receivers, so that each guest can hear the speech.

NEW WIRELESS TO ALASKA.



For years the only telegraphic communication with Alaska has been by way of the Sitka-Seattle and Valdez-Sitka cables. The growing commerce between Alaska and the States has resulted, as stated by H. Brown, commercial superintendent of the Western Union Co., in the establishment of an alternate wireless route by way of Astoria, Ore., which furnishes a telegraphic connection with a number of important points in Alaska.

Electricity Fills Important Rôle in Modern Automobile

THE automobile of to-day is rapidly coming to the point where everything in the operation of same will be controlled by a series of push buttons. We light the headlights, start the motor, or blow the horn by merely pushing the proper button, and now by means of the device illustrated at Fig. 1 we even shift the transmission gears. Instead of the usual wrist strain and noisy grating of the gear teeth that used to accompany any change of speed we merely select our speed, push the button and a touch of the clutch pedal does the rest.

This system is operated entirely by electricity and all the gear shifting done in the gear case by means of magnetic solenoids energized from a storage battery. Each of the solenoids is connected to its respective control button, mounted on the steering column, and a master switch is controlled by the clutch foot pedal. The switch here illustrated has three speeds forward and one reverse, which is sufficient for most ordinary work.

Some Late Electric Developments in Automobile Gear Shifting and Driving. Stars in Fig. 1 Indicate Electric Push Button Controller, Also Foot Pedal Control.

The operation of this apparatus is as follows: When the proper button is pushed it closes the circuit to the solenoid, which will throw the gears into the required position. The clutch pedal is depressed and when released closes the master switch, which throws an enormous current into the solenoid for a mere fraction of a second. The change of gears is accomplished so quickly that they mesh cleanly without a clash or any damage. This saves both the driver's temper and the cost of stripped gears.

It will be thought that nothing more could be devised in connection with the gear transmission, but in Figs. 2 and 3 we show a transmission mechanism which does away entirely with the necessity of a gear shift and yet gives a finer regulation of speed. R. M. Owen & Co., to whom we are indebted for the illustrations, call their car when equipped with this device "The Car of a Thousand Speeds."

This system of electrical transmission is as unique as it is flexible and consists of a generator, motor, storage batteries, resistance coils and controlling switches. The generator field is rigidly connected to the crank shaft as shown in Fig. 3, and the armature is connected to the driving shaft. The motor field is stationary and its armature, like that of the generator, is rigidly connected to the driving shaft as illustrated in Fig. 2. Thus it is evident that the generator field is revolved at engine speed, and both generator and motor armatures revolve at wheel shaft speed. The motor and generator are direct current machines; the motor being series wound, while the generator is shunt wound. This arrangement necessitates the revolution of the generator brushes at the same speed as the field. In order to deliver current to the brushes of the motor they are connected to slip rings, this same device being used for making connections with the field.

The complete system operates as follows: For cranking the generator is energized by current obtained from storage batteries, causing it to act as a motor, thus starting the engine in the same manner as the commercial motor starter now extensively employed. For starting the car a resistance is connected across the field of the generator, and as the magnetic flux builds up the field exerts a *torque* on the armature and turns the driving shaft and consequently starts the car. The resistance in the field is then cut out and short circuited, thus more current flows in the fields increasing the flux and exerting a greater torque on the armature which accelerates the car. The generator is constantly producing current due to the difference in speed of its field and armature. This current is led into the motor, which exerts a torque on the driving shaft and helps the generator to drive the car. To further increase the speed resistance is switched into the motor circuit, thus throwing more current through the field of the generator, which thus tightens its grip on its armature and decreases the *slippage* between the armature and the field. Successive resistances are cut in until practically there is no current drawn from the generator. The motor is then cut out of circuit and the generator armature feeds the fields only. The generator now acts as a magnetic clutch, the current necessary to energize is produced by a slight slippage between its armature and field which amounts to about 10 per cent. This slippage is sufficient to generate enough current to transmit 40 or 50 horsepower through the apparatus with high efficiency.

This may not seem possible, but it must be remembered that the slippage between the generator's field and armature has been decreasing as the car is accelerated, so that the relative speed of field to armature is small when this connection is made. With this small relative speed the armature reaction is not great enough to break down the torque. In this condition a point of equilibrium is reached where the slip is just sufficient to generate enough current to maintain the magnetic grip. The operation is analogous to that of the induction motor, in that an increase in load is balanced by an increase in slippage. If a grade is encountered the slip increases and because of this a greater torque is exerted on the driving shaft, due to the additional current generated.

All these operations are controlled by an extra lever situated on the steering wheel, thus eliminating the clutch pedal and gear levers. There is no flywheel, as the generator field acts as such. A mechanical brake is also provided, but this is not used except when it is necessary to bring the car to a sudden or dead stop. If the controlling lever is thrown to the neutral position when the car is running at high speed a resistance is thrown in series with the motor, which develops a torque that tends to stop the car. This brake will not bring the car to a dead stop as its braking power depends on the car's motion, but it is very useful in keeping down the speed.

The storage batteries are charged from the motor, which contains an auxiliary field that furnishes current to the batteries when it is on high speed. These batteries are used for lighting purposes.

With these rapid advances in the electrical equipment of automobiles we may safely predict that the car of the near future will not only be started, lighted and its speed controlled by electricity, but it will be steered by this willing servant of man. It will require no more effort to drive a powerful racing car than it does to call a waiter. The control of these machines will be so simple that a five-year-old child can handle one with ease.

NEW ELECTRICAL MANICURE.

Los Angeles ladies are having their nails manicured by electricity. It's the latest method of beautifying the hands. Pink powders and polishers are unnecessary on milady's toilet table, for the same electricity which has been harnessed for great industries does its little turn in milady's boudoir and polishes dainty fingers.

Mrs. F. A. Scott, of Los Angeles, who conceived this latest device for manicuring and beautifying, declares it trims, files, cleans, smooths and polishes the nails in a most sanitary, businesslike way.

B-r-r-r! and one's nails are filed and cleaned by a little whirring machine. A faster revolution and the nails are polished with a shine that won't come off—a shade pinker than seashells. A third pressure of the button, a louder b-r-r-r and a splash of toilet water, and the work is done. Why don't someone invent a machine to give the male of the species a shave, a massage and a hot towel automatically, and finally to release the "hat" without the everlasting "tip!"

Marvels of Modern Physics

By Rogers D. Rusk

Assistant Instructor in Physics, Ohio Wesleyan University

SOME MISSING LINKS.

IT is just as important that the scientific man should know about the stumbling blocks of science, as that he should have a well ordered knowledge of the facts and laws already determined.

Man has perplexed his mind with many difficult questions. In the physical field alone he has asked himself: Is space infinite? What constitutes matter? How does gravity act? What is electricity? Etc., etc., ad lib., ad infinitum.

Ages of weary labor have been expended on these problems with the result that we are hardly nearer the direct answers than we were before. Some of the blanks seem likely never to be completely filled, but at least we know more extensively and accurately concerning them and the phenomena to which they are related.

Most of the puzzle questions of the scientists have not been practical and worth while, however. It has hardly been 500 years since scientists were loudly wrangling over such frivolous and absurd questions as, "How many angels can stand on the point of a needle?"

It was in the midst of these absurdities that Roger Bacon made his remarkable prophecy in the thirteenth century, in which he predicted the coming of the steamboat, railroad and aeroplane. His prophecy is the more remarkable coming from such an age, but unfortunately he added that the fountain of youth would be discovered and the baser metals changed into gold. Like perpetual motion they have always proved to be the phantom at the end of the rainbow.

To-day, excepting, of course, the absurd and impossible, there are still many missing links in our chain of knowledge.

Some years ago Physics was defined as "the science of matter, ether and motion." These terms at once suggest to our mind three of our big *Unknowns*.

The last two of these will be treated of in this article, while the subject of matter and its constitution will be taken up separately later.

With reference to motion, the different kinds are pretty well known and understood. Of course many perplexing questions can be asked such as: "How can the top of a cart wheel move faster than the bottom?" and, "Can Achilles ever overtake the tortoise?" but these are more mathematical than physical problems.

Two of the forces which cause motion, however, are much less well understood. They are gravitation and magnetism.

Isaac Newton is popularly accredited

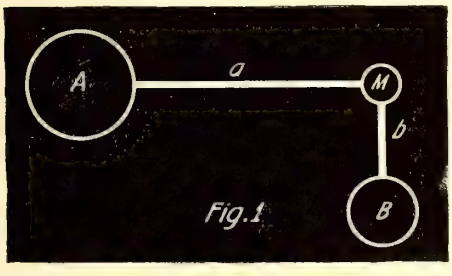

Fig. 1. Diagram Showing the Relative Pull of the Earth "B" and Sun "A" Upon the Moon "M."

with the discovery of the attraction which causes bodies to fall towards the center of the earth. Notwithstanding the familiar story of Newton and the falling apple, this force must have been recognized as a common fact long before his time. What Newton really did was to discover the universal law by which the force acted, and not the force itself.

This law—the universal law of gravitation—states that: "Every body in the universe attracts every other body, with a force that varies directly as the product of the masses and inversely as the squares of the distances."

This, of course, was a startling statement of the fact that the force we commonly term gravity is in reality a universal force acting between all bodies, and that it is only because the earth is so very large that it does not fall to the apple instead.

For a long time it was the pet dream of the more fantastic minded to discover a force of "negative-gravity" which would counteract or neutralize gravity itself, but the discovery of such a force seems quite far away indeed.

Newton's' law of gravitation brought out many interesting experiments. The sun,

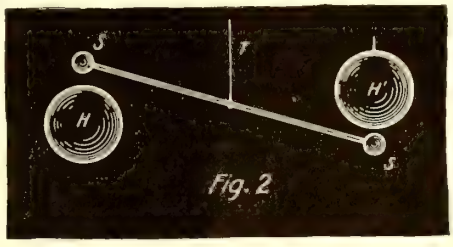

Fig. 2. The Famous Cavendish Experiment for Determining Relative Gravity Values.

moon and earth have each been weighed (a seemingly difficult task) by an application of this law. If in the diagram, Fig. (1) "A" represents the sun, "M" the moon and "B" the earth, while "a" and "b" rep-

Fig. 3. Illustrating Mechanically a Sphere Containing Opposite Electric Charges.

resent their respective distances of 93,000,000 miles and 240,000 miles, then the ratio between the relative pulls of the earth and sun upon the moon works out to be about $\frac{120}{54}$. This makes the sun approximately 300,000 times the mass of the earth.

Now to find the absolute weight of any of the bodies, the weight of one must be found before the proportion can be formed.

This was done by Cavendish in 1798 in his experiment which has since become famous. He definitely measured the attraction between a lead sphere 12 inches in diameter, weighing 350 pounds, and a smaller sphere two inches in diameter, weighing one pound and ten ounces, and also the attraction of the earth for same. The previous problem was really repeated by Cavendish substituting two lead balls of known weight for the sun and moon. Thus the earth with its thirteen billion billion pounds was actually weighed. In Cavendish's apparatus, in order to double the effect, two large spheres were used, and likewise two small ones. These are represented in Fig. 2, and the small ones as shown were connected by a light bar and

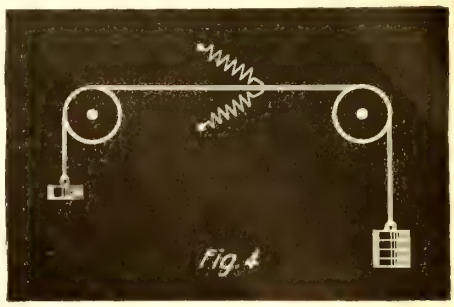

Fig. 4. Mechanical Analogy of Electric Strain Existing in a Charged Leyden Jar.

suspended by a thin silver wire. The amount of twist of the wire was then a measure of attraction between the spheres.

Many theories as to the nature of the force of gravitation have been presented, but the only theories which seem at all reasonable or possible imply the existence of some invisible and intangible medium which exists throughout all space, and permeates all matter; which exists between the heavenly bodies, beyond the limits even of any atmosphere.

In following this line of thought we are treading exactly in the footsteps of the older scientists, beginning with Newton.

Little of a definite nature was done with reference to the establishment of such a theory until 1678, when Huyghens, perceiving that light traverses a vacuum unimpeded, decided that it must have some medium to travel in or on. Also, as light comes from the sun, and even from the most distant stars, this medium must indeed be infinite in extent. Earlier theories of light had miserably failed, but Huyghens formulated his theory that light is nothing material, but that it is a wave motion in some invisible medium, which medium we call the *ether*.

Wonderful to relate, this theory, with the exception of a slight modification along electro-magnetic lines by Clerk Maxwell and others, is the accepted theory of today.

The development of our theory of the ether has been the biggest unifying factor in the history of modern physics. It has brought the different branches of physics in close touch, and paved the way for wonderful future progress.

There is little more to say concerning gravitation until we have considered the ether further.

Is the ether material or not? Matter is that which occupies space, but the ether does not occupy space in the ordinary sense of filling space. It is intangible and imponderable, therefore we say it is not matter; but on the other hand if matter is that which *exists*, and has certain physical characteristics, then ether may well be classed as matter. The horns of the dilemma are obvious.

Some years ago the ether was characterized as continuous (not composed of unit particles), infinite in extent, infinitely elastic, frictionless and without weight.

Sir William Thompson, however, made the interesting calculation, dependent on the displacement of a particle of ether in

Baron Münchhausen's New Scientific Adventures

By Hugo Gernsback

The Cities of Mars

MANY of our astronomers have noted from time to time that immense sandstorms frequently sweep over the face of the Planet Mars. As such storms seem to cover vast areas it would appear that the sand must of necessity be rather light to float in the thin Martian atmosphere. For this reason, it is reasonable to suppose that the sand is extremely fine—dust in other words. But how can intelligent beings live permanently in an atmosphere loaded with fine dust? This instalment advances a new idea how the Martians may make life bearable on their desert planet.

IF there is one thing that annoys me, it is a nosey reporter. To be sure, they are harmless folk, are reporters, and suave and well-mannered as a rule, too. But somehow their eyes always appear to me as gimlets and their noses as huge corkscrews, but then those are the characteristics of the tribe, and really they can't help it. It is their business to drill holes right through your mind, and once their corkscrew noses have dug themselves into your confidence they pull and pull till something comes up. A reporter can always dig news out of you, even if there's no news to be had. All of which might be of interest to you, and then again it might not. At any rate, the editor of the Yankton *Bugle,* who has heard about Münchhausen, sent a reporter to my laboratory in order to "write me up" and to find out if Baron Münchhausen was fiction or truth. Not that it was the first time that this particular reporter had called in vain. For I have a deep-seated aversion against the *Bugle,* which aversion includes everyone from the editor down to the job press. Hence I wasn't "in" to reporters heretofore. But on this occasion the reporter, who is a live one, succeeded in running the blockade. He "made up" as a water meter inspector, and as both the water meter, as well as my wireless station, are located in the basement of the house, he had but little trouble in "torpedoing" me. Once established in a chair there was nothing to do but to submit to his tortures.

Of course, he did not believe that there was such a thing as Münchhausen, who was supposed to live on Mars just now and who was supposed to send nightly wireless messages to earth, which are relayed to me from the moon by an alleged relaying plant located there.

However, the reporter was willing to obtain first hand evidence for his paper, and if I did not object very much he would stay till 11 p. m. in order to "listen in." To strengthen the argument he pulled out some two for 50c. Perfecto's (reduced to 40c. Saturdays only at Frank Levoy's cigar store on Main street). As my Nargileh wasn't working for lack of proper ammunition that evening, the argument proved convincing and I bade the reporter, whose name was Bill Snickles, to make himself at home. I explained to him all the good points and qualities of my wireless, and after the second Perfecto I was willing to let him photograph the station. He called up the office for the staff photographer, and after the flashlight had been taken it became time to adjust the instruments. In another three minutes Münchhausen would be calling. I had placed an extra set of 'phones on Snickles' head and I could see that he was breathing hard with suppressed excitement. I had keyed him up to such a pitch that when my chime began striking the first stroke of eleven he jumped clear out of his chair. But I smiled a very superior, benevolent smile at him, as a father smiles at his uncomprehending babe. I then leaned back comfortably, toyed a bit with the Harmonic Ultra-Amplifier, adjusted the Selenium Vapor Enforcer, and turned once more the knobs of the coupled inductance balancer to make sure that I was tuned in for 90,000 meters—the wave length used by Baron Münchhausen.

The chime had sounded its last stroke. In another second the dear old gentleman's voice would greet me as usual.

Have you ever wished to "show off" to your friends or to your relatives and the "show off" failed to materialize? Have you ever experienced the cunning feeling of an icy cold wave racing up and down your spine, to be followed immediately by a hot blast up and down the self same spine? And has the perspiration broken out all over you at the contemplation that the "show off" was a fizzle? Yes? If you have, you know exactly how it feels.

At 11.05 p. m. I began to wonder why it was so hot in the room. By 11.10 p. m. I was taking a Turkish bath. By 11.20 p. m. I calculated that my private temperature must have gone up to somewhere near 269° Fahrenheit, rising steadily all the while. By 11.30 p. m. I wasn't sure whether I preferred calling an ambulance or jumping into the ice covered pond in front of the house.

Münchhausen simply didn't "call." What was wrong? Why had he failed me for the very first time, just when I could least afford it? For the first time since I knew him I felt bitter toward him. What had happened?

And there was Snickles with a sarcastic grin spread all over his bird-like face, making biting remarks all of the time.

"Maybe the ether gave out, what?" he mocked. Or: "Maybe Münchhausen has a Martian frog in his throat and can't talk!" Or else: "Isn't it possible that the message became lost in transit? In that case I would suggest that you put an ad in the *Bugle's* Lost and Found co....."

That was the last straw. He didn't finish the sentence and he didn't wait to take his hat either. He went out like a blue streak, with me at his heels. But reporters, among other accomplishments, must be good runners. He is. At any rate, I did not catch him. Disgusted and in a white rage, I went to bed.

My ruffled feelings were not particularly smoothed next morning when my young brother brought me a copy of the *Bugle* while I was still in bed.

Snickles had certainly outdone himself. The whole town would choke with merriment when they would read the account, there was no doubt about that. The headlines were enough:

I. M. ALIER MAKES STUPEFYING INVENTION.

RECEIVES SOUNDLESS, VOICELESS, MESSAGES FROM MARS.

ALLEGED HERO, MÜNCHHAUSEN, SPEECHLESS WITH SURPRISE.

MÜNCHHAUSEN SAYS HE AIN'T SAYIN' NOTHIN'!!

And so on, and so forth. The article was written so excruciatingly funny that I had to laugh myself, despite my rage. But the laugh froze to ice when my eyes had passed over the line where Snickles had written ironically:

"Undoubtedly Münchhausen was asleep at the switch!"

With one bound I was out of bed and was racing madly down to my wireless station barefooted. I gave one look at the lightning switch in the corner of the room and almost collapsed:

The switch was grounded and had been grounded since noon of the previous day!

For you may know that the Fire Underwriters nowadays require wireless stations to have lightning switches in order to protect the building from lightning. Thus when your station is not in use you simply connect the aerial to the ground by throwing the switch, and no damage can be done by a thunderbolt. Not only that, but in this condition the aerial becomes really a first class lightning arrester.

Sad to relate, however, certain idiots are apt to forget to throw the switch over when trying to receive messages, I being among them that evening. For when the reporter called so unexpectedly I forgot all about the switch and never bothered to look around to see in what position it was.

Münchhausen had called, of course, of this I was certain. The message, however, had flown from the aerial directly to the ground, never entering my receiving instruments Lost and lost forever! And my thoughtlessness had made me the laughing stock of the town on top of it! It was maddening. Right then and there for the next ten minutes I had what my little sister very appropriately terms as a series of rather violent "conniption fits!"

* * * * * *

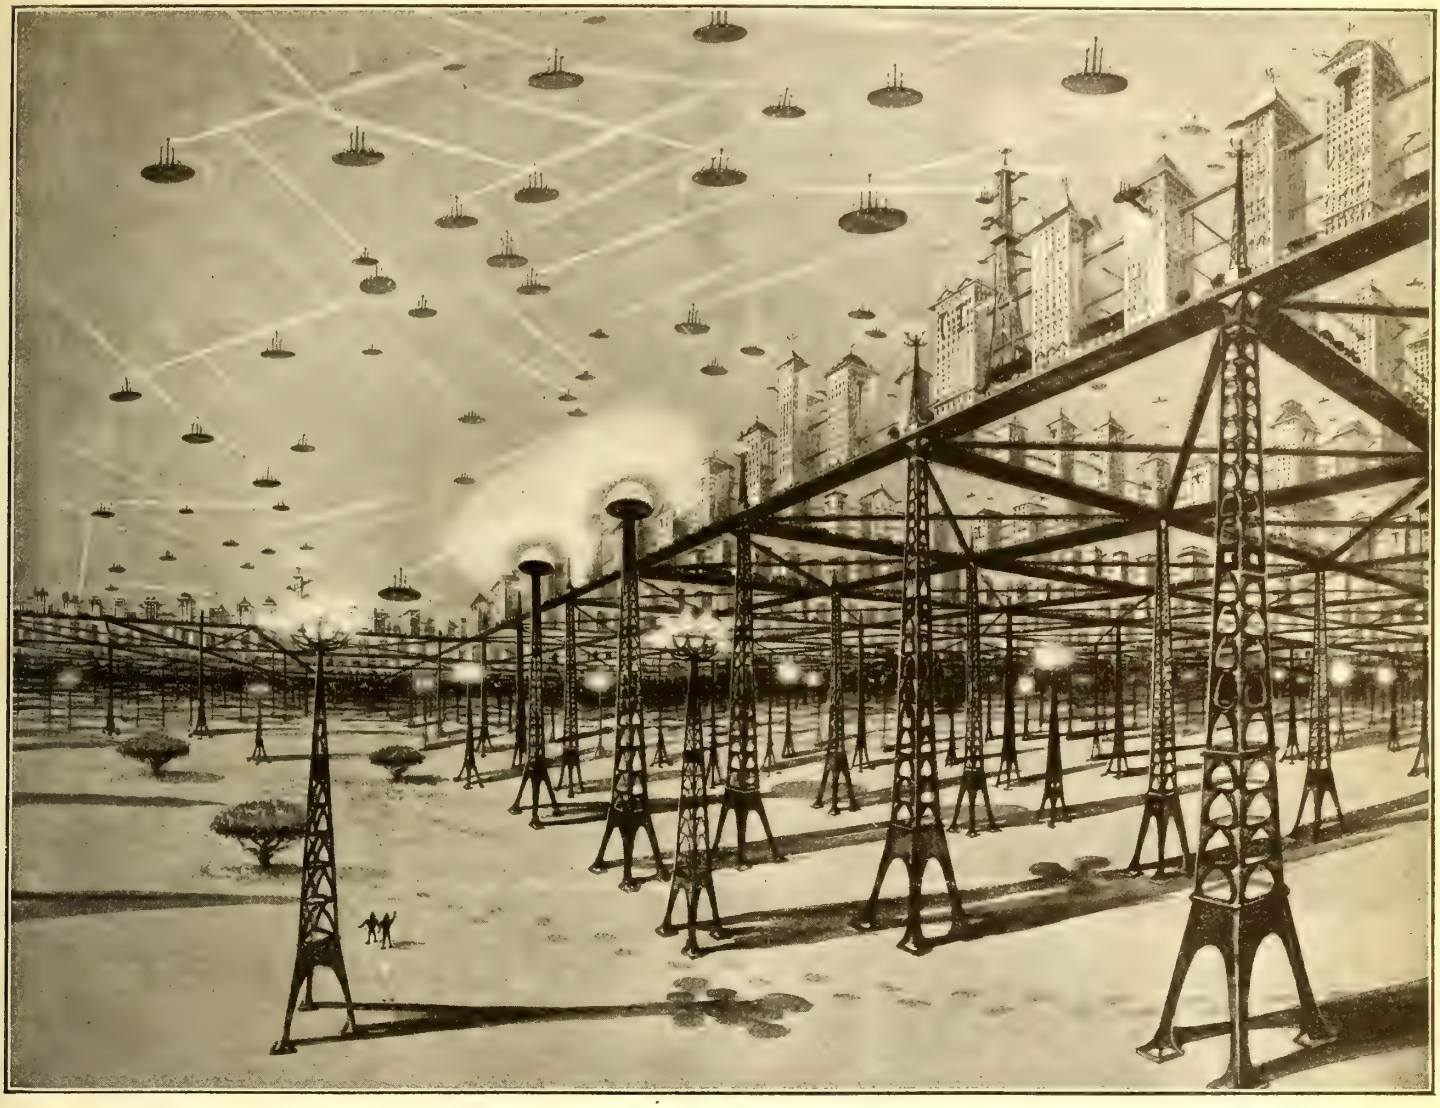
That evening promptly, as always, Münchhausen "called." He did not waste much time in preliminaries, but went right to the point:

"Alier, my dear boy, I can't begin to tell you how wonderful this planet Mars is with all its marvelous inhabitants. Flitternix and myself are as in a trance half of the time. Our brains simply cannot digest all the thousands of wonders we see around us every minute. For a poor untrained human mind to be suddenly transplanted into a civilization hundreds of thousands of years ahead of terrestrial civilization is no easy matter. At times we are positively numb with astonishment and the more we see and learn the less we feel we know. Every new marvel opens up a dozen new unfathomable avenues, each one equally puzzling.

"But to proceed. Yesterday I explained

Copyright, 1916, *by H. Gernsback. All rights reserved.*

to you how we had our first Martian meal at our host's residence and how we experienced that gaseous food that you don't need to chew, is vastly more nourishing and satisfying than solid food. It does not overload the stomach as do solids and the digestion is vastly improved. The gases liquify, of course, in the stomach, but the latter itself never becomes distended. Besides, the Martians, trained rigidly from earliest childhood, know just how much gaseous food they can assimilate. This, I understand, is one of the reasons why the average Martians live over 150 Martian years, which is 300 terrestrial years.



"After dinner we were conducted to the roof of our host's mansion, where we made ourselves comfortable in the large transparent chairs scattered around beneath a cool, green, silky-appearing canopy. As I mentioned to you previously, the Planet Ruler's mansion resembles somewhat a colossal cathedral. The roof is about 250 feet from the ground and the entire structure rotates slowly around on its axis. This is the reason: While the Martians are enlightened enough to have no religion whatsoever, they know what we have known for some time, namely, that life on all planets is absolutely dependent upon the sun. Extinguish the sun to-day and all the planets throughout our planetary system from Mercury down to Neptune will become dead worlds. Without sunlight the rivers will cease flowing within three weeks. Within six months all waters on earth and Mars will have frozen down to the bottom. The vegetable kingdom will have ceased long before that and the animal kingdom, dependent upon the vegetable kingdom, will die even a more rapid death. In less than two years the last surviving human on any of our planets will have ceased living. There can be no organized life as we know it without the direct influence of a live sun.

"While the Martians are by no means sun worshippers, they nevertheless have a deep-rooted feeling for our luminary. This is strikingly illustrated by the fact that the Planet Ruler's mansion is constructed in such a manner that powerful machinery revolves the entire structure silently during the entire Martian day; the first rays of the morning sun thus shine into the Ruler's private rooms, and as the sun keeps on rising the house keeps pace and thus the entire day till the last sun ray creeps over the western horizon, the Ruler's windows are bathed in sunlight. During the night the house does not revolve.

"The day we were on top of the Ruler's mansion was still our first day on Mars. It was then in the early afternoon, after lunch time, as mentioned before.

"Down below we looked upon the 'city,' which seemed to be laid out in form of a vast semi-circle, as far as we could ascertain. To the west we could just glimpse one of the water ways.

"We stepped to the balustrade and peered down, completely stupefied with what we saw. But Flitternix, his mind full of astronomical observations, called my attention to the heavens and I followed his command reluctantly.

"It was found that the ordinary desert dust did not usually rise higher than 400 feet above the surface of the planet. For this reason all buildings and structures on Mars, with few exceptions, are located 500 feet above the ground. . . ."

"'You will observe,' said he, pointing at the sun, 'that it appears quite a bit smaller than when seen from the earth. It also does not appear yellow-white, as it looks to terrestrial inhabitants. You will note it has a rather reddish hue; that is because we are now a good bit further away from it, a matter of over 60,000,000 miles further than on earth. In other words, we are now twice as far away from the sun as we are on earth. But you must have observed how warm it is everywhere on Mars, as far as we have visited it, and that the day appears fully as bright, if not brighter, than on earth. Naturally you will wonder, for on Mars, as well as anywhere else in the world, certain physical laws hold good. Thus heat and light diminish inversely as the square of their distance, in other words, a 16 candlepower lamp two feet away gives only one-quarter the light (four candlepower) of the same lamp if seen at one foot away. Heat acts in exactly the same manner. Then why is it that the day is as bright, and the heat as great as on earth, although we are twice as far removed? According to the physical law just mentioned Mars should only receive four-ninths of the light and heat from the sun as does the earth. Why does it receive more? Early astronomers on earth rea-

The RADIO LEAGUE of AMERICA

HONORARY MEMBERS
CAPT. W.H.G. BULLARD, U.S.N. NIKOLA TESLA.
PROF. REGINALD FESSENDEN. DR. LEE DE FOREST.

Manager, H. Gernsback

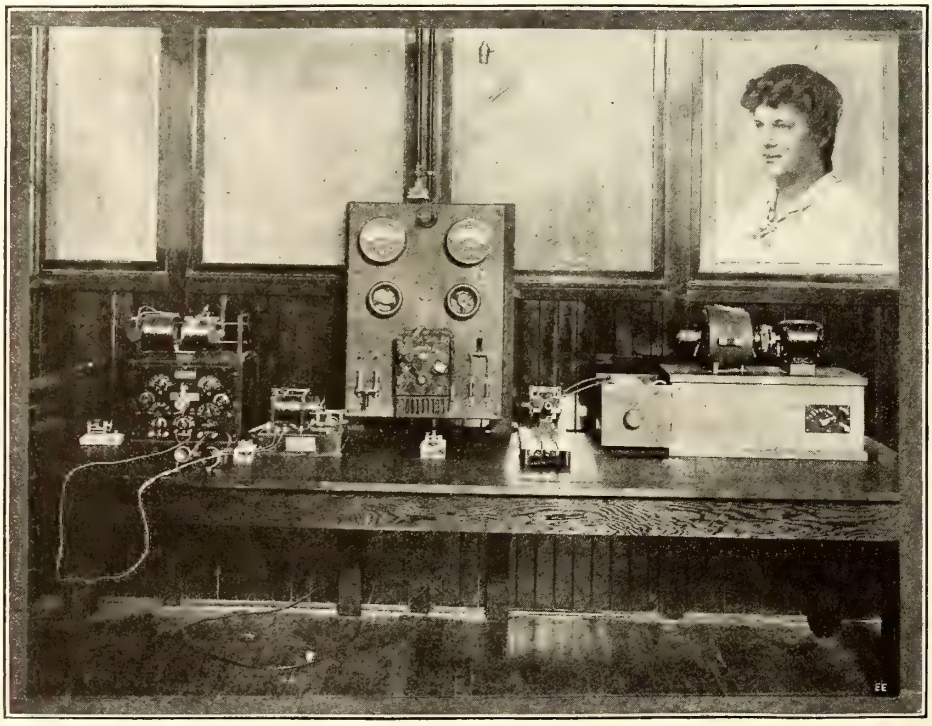
How to Organize and Conduct a Radio Club

WITH the advent of The Radio League of America, the details of which organization were given in full in the December, 1915, issue of *The Electrical Experimenter*, there has been opened up a wider and more promising field than ever before for the formation of subsidiary or local radio clubs throughout the country. Given the proper spark of enthusiasm, there is no city or hamlet too small in the whole United States but what it could support one or more such radio clubs.

Possibly you, as a radio enthusiast, even though you may not have a very elaborate wireless station (either for receiving or transmitting, it matters not), have often thought it would be a fine idea if you could band together several other similarly interested persons either from an experimental, scientific or amateur standpoint.

Preliminaries.

To start a radio club or society there are several methods which may be employed to aid the formation of such. One of the first things that can be done is to write a letter to the manager of the Radio League of America stating briefly your intentions and desires, at the same time asking for the names and addresses of any other radio amateurs in your particular locality. Upon receipt of this information you can then either visit the experimenters personally or a very good scheme is to write each a letter, explaining your ideas and suggesting a date for a meeting at which the matters pertaining to the formation of a local radio club can be talked over.



In some cases such organizations are formed and many details of the work are finished *via wireless*, as, for instance, when the "organizer" has a radio transmitting and receiving station so that he may call up other amateurs by noting their call numbers in the regular Wireless Call books. Still another scheme which can be followed out in many such cases, and also at an insignificant cost, is to insert an advertisement in your local newspaper, stating that the advertiser would like very much to have all those interested in experimental wireless telegraphy call at his residence on an appointed evening for the purposes set forth.

One of the first things that has to be considered after a response has been had to such an advertisement or other campaign as aforementioned, is the rules of order to be followed in forming the organization. It may be said that many small clubs do not go in for the deeper legal rules usually governing such bodies. The appointment of an inspector or engineer as one of the officers, together with the president, vice-president, secretary and treasurer (the two latter officers are very often combined) suffice for all practical requirements.

It is a very good idea to select a capable member to act as consulting engineer, and whose duties shall cover the visits to each member's station for the purpose of checking up his wave length, deficiencies in operation of the apparatus, etc.

Maintaining Interest in the Club.

Once the radio club has been formed, it is not always an easy matter to maintain the interest in same by the members. A good leader in any event will help to overcome this trouble to a large extent, but of course he must be aided in every way by the other officers of the club. One of the first important things to be done when starting a new organization is to select for the first few meetings, at least, some particularly good wireless or allied papers. They advisedly should not be of too technical a nature, as it may discourage some of the younger members or others who are not so far advanced in the science. A good suggestion in this direction is, whenever possible, *try to obtain the services of an instructor in radio operating and engineering from a local school or college*, who in most instances will be only too glad to make a short address at any time, before such an organization.

The Very Fine Radio Equipment of the Minnesota Wireless Association, Minneapolis, Minn. Insert Photo Is That of Miss Aline Mengelkoch, a Radio Enthusiast, Who Often Operates the Set Here Shown.

A letter of the proper sort, addressed to such men, will invariably result in their acceptance of your proposition. It will be readily seen that a greater impetus will be given the club if such speakers are engaged at least for the first few meetings. A case in point is the Radio Club of America, with headquarters at New York City. This organization has been coming to the front very rapidly in the past two years. Many of the speakers at the monthly meetings are some of the leading instructors and engineers in the wireless profession; men who also address meetings of the Institute of Radio Engineers, which body is, of course, the foremost scientific radio organization in the world, counting among its members the leading wireless engineers and scientists of all countries. The office of the secretary of the Institute is at 233 Broadway, New York City. The monthly meetings are held on the first Monday of each month in Fayerweather Hall, Columbia University, New York City, at 8 p. m. This Institute publishes its proceedings, containing the more important articles presented at the various monthly meetings, four times a year; that is to say, the proceedings come out quarterly and form a most valuable addition to any radio operator's or engineer's library. The dues for an associate membership are $4 a year, and so far the Institute has managed to publish its proceedings and defray its other incidental expenses with but little extra financial aid from a few of the members.

It is not intended to dwell upon the features of such an extensive body as that now under discussion, but it may be said that while the interest among the members has flagged at different times, notably several years ago owing to the great shake-up in the business affairs of several commercial wireless companies, etc., it should be said that those managing the affairs of this organization have always kept in mind the point previously mentioned, i. e., that it is best to obtain the services of the very best speakers and lecturers in this line whenever possible.

The small radio clubs just forming, however, need not feel discouraged if they cannot obtain a speaker of prominence or great learning to address them, as in many instances there are one or more energetic and capable radio men among their own members who will probably in many cases

prove better as leaders for such bodies of youthful experimenters than a more mature individual of more advanced and professional inclinations.

Club Dues.

Speaking of club dues, this is an important point. As many of these societies meet at the members' houses, there is then no rent to be considered. The smaller clubs, of course, can run along quite nicely with but a small budget or expense, except that necessary for buying stationery, having cards or literature printed, etc. For the younger clubs, composed of members between the ages of 12 and 15, the dues should not reach much above 25 cents a month. But with clubs made up of older members than those just mentioned and having club quarters for which rent must be paid there will, of course, have to be a higher monthly due levied. Most of the larger organizations have an entrance or initiation fee of perhaps $1, but this, of course, will have to be considered and worked out by the officers in charge of the affairs of the club. This factor will vary in the different localities and with the different classes of members.

Investing in the Club.

While it is not desirable in any event to work hardships upon the members of the radio clubs, it should be borne in mind by the officers of such that the organizations enjoying the greatest popularity are those in which the members are very vitally and personally interested. This comes to the point of having each member invest in the club, which may be brought about by bringing the propositions before the organization at one of the regular meetings. A great many of the societies to-day have excellent wireless sets maintained at the club quarters and, of course, in this instance the rooms are invariably open every day, or at least every evening, so that those members who so desire may come to the rooms for practice or training in the handling of the radio apparatus. There should be a chief operator appointed, and also when occasion demands it, someone who shall be responsible for the proper maintenance of the wireless set.

It is best to choose a fairly good wireless transmitting and receiving set, which can, of course, be had at all prices imaginable, say from $10 up, and even for a lesser amount when the club is a small one.

Excellent Wireless Exhibit of the Atlanta Radio Club, of Atlanta, Ga., an Example of What a "Live" Organization Can Accomplish.

In this direction we would like to call the reader's attention to the excellent photographs reproduced here and in other forthcoming issues of *The Electrical Experimenter* showing what can be accomplished by a good, "live" amateur wireless organization.

In the first illustration we wish to mention the excellent wireless set owned by the Minnesota Wireless Association, of Minneapolis, Minn. Particularly in this connection we wish to call attention to the excellent work accomplished on this outfit by Miss Aline Mengelkoch, whose picture is observed in the upper right corner of the illustration of the station. Miss Mengelkoch is very enthusiastic about wireless telegraphy and is said to be the youngest commercial woman operator in the United States, she having just received a first-class Government radio operator's license. She can transmit and receive messages at the rate of 35 words per minute and, moreover, is widely read on the subject of radio telegraphy.

This is a good matter to keep in mind in club affairs. Do not forget your sister or girl friend who may have scientific inclinations. Get her to join the club, as there is a wide field open, indeed, for wireless experts, and the excellent work of Miss Mengelkoch before cited, as well as that of several other women operators, proves that she can engage in this field as successfully as in any other.

While on the subject of amateur wireless clubs that are doing big things, we would call attention to our illustration which represents the excellent wireless exhibit conducted by the Atlanta Radio Club, of Atlanta, Ga. The address of the vice-president of this club, R. A. DeVore, is 19 Second avenue, Oakhurst, Atlanta, Ga. It is really wonderful to contemplate the achievements of this organization, which was started but little over a year ago. It has received many congratulations on the exhibit which it arranged and which formed a part of the recent Electrical Show held in Atlanta.

The exhibit attracted great attention. One of the most interesting features, perhaps, was an exact replica of the first Marconi wireless set, complete with induction coil and coherer. Near this was a complete sending and receiving set of modern type, owned by member of the club, with which bona fide radio messages were received and transmitted. The visitors to the show were given popular lectures by members of the society on the theory and practice of wireless telegraphy, and, together with practical demonstrations, they were made to appreciate the rapid strides made in radio work the past few years.

The Electrical Show was held on the ground floor of a large office building, upon the roof of which was erected an aerial, the height of which was nearly 200 feet and the total length 400 feet.

Another point of interest was a table 5 by 15 feet, completely covered with send-

REVISED LIST OF AMATEUR RADIO CLUBS

Akron Radio Club, 760 Damon place, Akron, O. Secretary, A. A. Crum, Radio department, G. T. & R. Co., Akron, O.

Amateur-Scientists, Public School 66, room 256. Secretary, Harry Fienberg, 124 Amboy street, Brooklyn, N. Y.

Amateur Marconi Radio Association, 614 Fifth avenue, Troy, N. Y. Secretary, D. Malcolm Williams, 1627 Seventh avenue, Troy, N. Y.

Bradentown Radio Club, Stockbridge avenue, Bradentown, Fla. Secretary, Hughson Hurlebaus, 439 Main street, Bradentown, Fla.

Carrollton Radio Intercommunication Club, Fifth Street Public School. Secretary, Stuart W. Pierson, 214 Maple avenue, Carrollton, Ill.

Chicago Wireless Association, room 1010 Lake View building, 116 South Michigan avenue, Chicago. Secretary, Frederick D. Northland, 24 Scott street, Chicago, Ill.

Colorado Wireless Association, 600 Y. M. C. A. building, Denver, Col. Secretary, L. P. Hough, 600 Y. M. C. A. building, Denver, Colo.

Cranford Radio Club, Cranford, N. J. Secretary, Russell Damon, Arlington road and Madison avenue, Cranford, N. J

East Night High School Radio Society, Woodward High School. Secretary, C. H. Fender, Woodward High School, Cincinnati, O.

Fall River Radio Association, Technical High School, Fall River, Mass. Secretary, Lawrence Phelan, 6 Rodman street, Fall River, Mass.

Hawkeye Radio Association. Secretary, A. B. Church, Lamoni, Ia.

Inter-City Radio Association of Allentown, Pa., Y. M. C. A. building. Secretary, William J. Kreis.

Junior Radio Club, Gregory street, Pensacola, Fla. Secretary, Oliver Williams, Pensacola, Fla.

Philadelphia Radio Association, 4810 Germantown avenue, Philadelphia, Pa. Secretary, G. S. Ballantine, 4810 Germantown avenue, Philadelphia, Pa.

Radio Club of the Polytechnic Institute of Brooklyn, 85 Livingston street, Brooklyn, N. Y. Secretary, R. G. Wehle, 85 Livingston street, Brooklyn, N. Y.

Radio Club of Union College, Union College, Schenectady, N. Y. Secretary, Edwin A. Schabbehar, 242 Union street, Schenectady, N. Y.

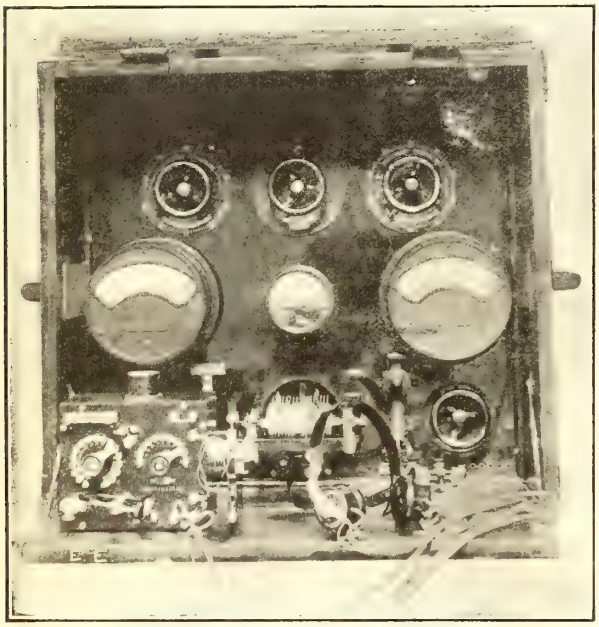
Rockaway Radio Club, 296 Washington avenue, Rockaway Beach, N. Y. Secretary, L. Wagerer.

The Talo Club, New York City. Secretary, Edward T. Dickey, 1649 Amsterdam avenue, New York City.

Technical Wireless Association, Washington, D. C. Secretary, Edwin D. Powell, 908 Kennedy street, N. W., Washington, D. C.

Wireless Association of Central Pennsylvania, Harrisburg, Pa. Secretary, D. H. Zorger, 409 Kelker street, Harrisburg, Pa.

Yorkville Radio Development Association, 73 East End avenue, New York City. Secretary, Joseph L. Cermak, 73 East End avenue, New York City.



Notice: To ensure proper entry of club registrations in our revised monthly list be sure to send us at once the data outlined below. Such information should reach us not later than the 28th of the month for entry in the succeeding issue of THE ELECTRICAL EXPERIMENTER.

Name of Club .....
Location (street and city).....
Founded .....
No. of Members.....
Meeting Date .....
Power of Club Set, if any.....
Call Letter (licensed?).....
Dues and Initiation Fee.....
Secretary's Name and Address.....

New 500 Watt Military Radio Pack Set

THE wireless sets used for military purposes, and particularly those now in use by the United States army, consist of the very best instruments that can be purchased. These sets must work under every possible condition. The accompanying illustration shows one of these extra sturdy pack outfits, which at the same time combines extra high efficiency in both the transmitting and receiving ranges attained, as well as in small space occupied.

Extremely Compact 500 Watt Military Radio Set.

These sets are of the portable style, equipped with generators of the 500-cycle alternating current type fitted in a separate case, so that it is thoroughly portable and may be carried on separate trucks. The cases are unique in construction, consisting of a substantial wooden frame or base, so to speak, which is covered both on the inside and outside with a 1-16 inch layer of gray sheet fiber. This is glued to the wood under hydraulic pressure. The cabinets are protected by hard fiber angle strips riveted on and further protected from damage by iron bumpers at the corners.

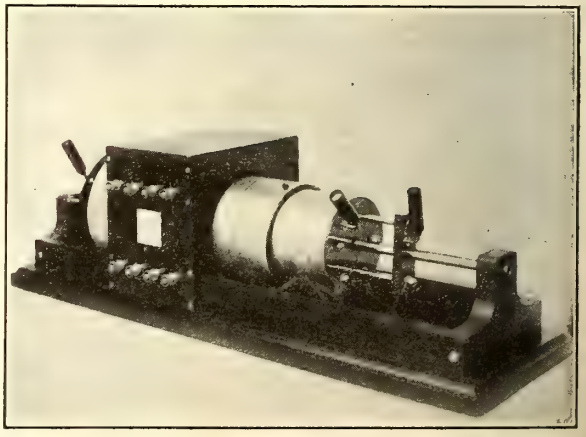
The apparatus, such as volt-meters, ammeters and hot wire meter, as well as transmitting inductance control handles, etc., are all mounted on the micarta panel. The quenched spark gap of special design, perceived at the base of the panel, is cooled by a small electric fan placed behind it, so as to blow a draft of air directly over the gap. The gap plates rest in micarta guides. Their sparking surface, which is at the center, is of pure silver. This surface measures 3-64 of an inch in thickness, with a diameter somewhat larger than that of the metal plates supporting them and on which they are soldered. The silver is then spun over and riveted down.

The condenser bank for this 500-cycle transmitting set is composed of six condenser units of practically .002 micro-farad each. The resulting capacity of the whole bank, after the condensers are connected in series-parallel, is .013 micro-farad.

The step-up transformer, of the resonance type, is of the open-core pattern and is mounted within the case, back of the micarta panel containing the measuring instruments, etc. Silk-enameled magnet wire is used in winding the secondary of same, which is of the dry form, not requiring any oil for its insulation. Various transmitting wave lengths may be quickly arranged for by means of calibrated inductance control handles and scales mounted on the front of the upright panel of the set. A regular Morse key is perceived at the right of the cabinet

The receiving set is very compact and may be observed resting on the drop front of the transmitter cabinet, at the left of the illustration. The head 'phones are the well-known adjustable-magnet type supplied to the United States army and navy, and in which the distance between the pole-pieces and the diaphragm may be varied as required for different strengths of signals by means of an adjusting screw at the back of the receiver case. The receiving set is a beautiful piece of apparatus, which includes a Pyron detector. The primary coil of the loose coupler is wound with 170 turns of No. 22 enameled copper wire, divided up into two sections, one of 10 turns and one of 150 turns. These are suitably connected up to switches, so that any combination of turns, from one to maximum, may be obtained rapidly.

The whole receiving set is installed in an oak cabinet with hard rubber top and end, upon which the switch points are mounted. It also contains a series condenser for short wave lengths, but which unit is normally short-circuited by a special switch. The secondary is also adjustable as to the inductance, and as it slides out of the primary cabinet its graduated tubular covering indicates the percentage of coupling. Photo courtesy Wireless Specialty Apparatus Co.



A NOVEL RADIO INDUCTIVE TUNER.

Since the introduction of the loose coupler there have been few, if any, radical changes in the design of same. The change from sliders to tapped coils was so slight as to make very little improvement, so it remained for a radio engineer of a later day to devise the apparatus shown herewith.

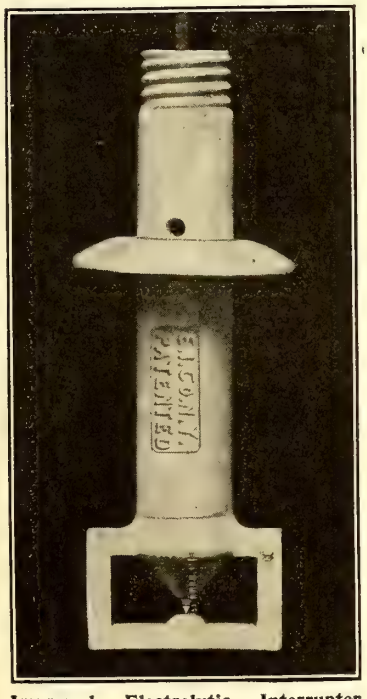
The old type of inductive coupler was adjusted in steps, which did not give very close tuning, and the presence of large amounts of unused wire created the bugaboo of all previous tuning apparatus, namely, "dead-end" effects, which absorb considerable energy and destroy the efficiency of the apparatus. To offset the above defects it was the general practise to use variable condensers to secure accurate tuning, and many complicated switches were devised to prevent the dead-ends. The coupler illustrated herewith does not require any taps or variable condensers, all the wire on same being in use at all times. A brief resume of the principle of this instrument will not be out of place.

The primary consists of two coils, one permanently fixed in the box, shown in the illustration, and the movable one shown at the left. These two coils are wound to have an equal amount of inductance, but in opposite directions, so that when the movable coil is slid entirely into the fixed coil the sum of their inductances will be zero, because they oppose and counteract each other.

The same principle is used in the construction of the secondary, which consists of two coils shown protruding from the end of the box to the right. These coils also have the same amount of inductance, and they also counterbalance each other when the inner coil is entirely within the outer coil. It will be apparent that when withdrawing the inner coil the exact balance of the two inductances is upset and the circuit will possess an inductance depending upon the relation of the two coils. By this simple means it is possible to adjust the active inductance in either circuit, thus doing away with all taps or sliders.

New Loose Coupler, Adjusted Without Sliders or Switches.

The secondary coils may be moved inside of the primary coils, so that by varying the inductance relation between the two sets it is possible to vary the coupling.



The many advantages of this apparatus will now be readily understood, for it gives

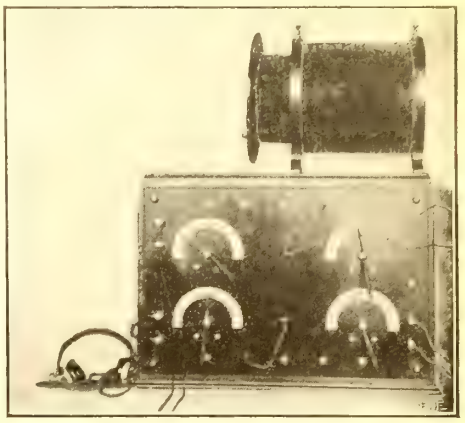
(*Continued on page* 667.)

NEW ELECTROLYTIC INTERRUPTER ELECTRODE.

An improved form of positive electrode or anode for electrolytic interrupters has been perfected by a well-known New York experimental supply house. The tube is shown in the illustration herewith. It consists primarily of a specially designed porcelain tube, which carries a thread at its upper end, intended to screw into a porcelain cover. A metal rod made of a special alloy passes down through the interior of the tube, and the point of same protrudes through a small orifice slightly larger than the rod at the base of the tube proper, as perceived. The metal wire point rests on a porcelain bridge, as illustration portrays, so that excessive current will not be drawn. Any electrolyte which may find its way into the interior of the tube by working in around the metal rod will be ejected through three small perforations in the wall of the tube just above the porcelain skirt formed on the tube about two-thirds of the way up, as perceived.

It is claimed that this marks a great advance in the design of such devices and actual laboratory tests have demonstrated that for operating wireless coils, X-ray coils and open core transformers up to one kilowatt capacity there is nothing superior to it. It will work on either A. C. or D. C. circuits at 110 or 220 volts potential and on any frequency. *The key may be held down for periods of one-half hour or more* and the interrupter will work regularly and without undue overheating. An interesting point is found in the fact that the lower end of the rod during operation wears away to a *perfect* sharp point. The rod which is consumed slowly in operation is fed down automatically by gravity. It offers a practical solution of the power transforming problem constantly confronting the wireless and electrical experimenter, especially where he desires to utilize the commercial power circuits to operate his spark coils and the like, and where he desires to utilize direct current on an open core transformer. Such interrupters are not adapted for operation with closed core transformers.

Improved Electrolytic Interrupter Electrode Recently Brought Out. The Metal Rod Cannot Drop Through the Tube, Owing to a Porcelain "Bridge" Formed as Shown.



AN UNDAMPED WAVER.

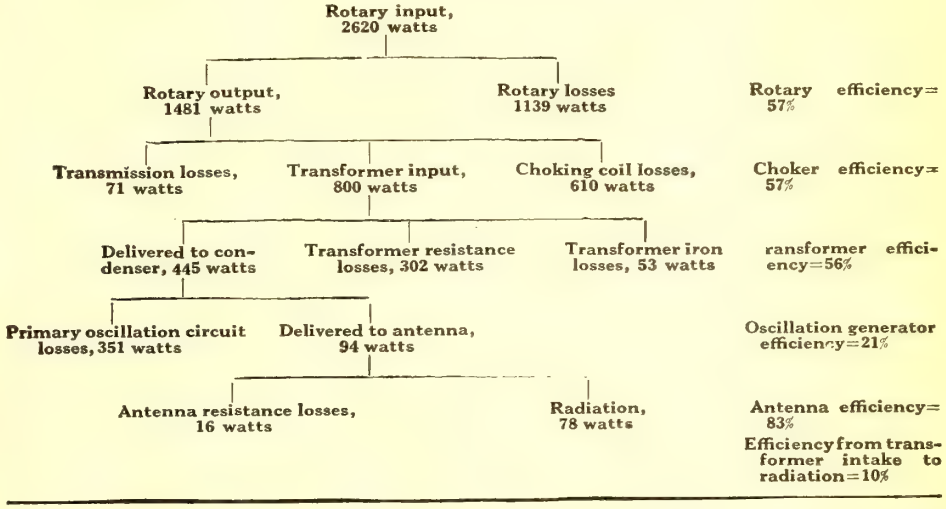
A great deal of speculation has been made during the past two years by the majority of amateurs in regard to the reception of undamped waves emitted by the powerful radio stations about the globe; practically all the long distance transmission records have been accomplished only by the use of undamped waves.

The ordinary radio receiver is deaf, so to speak, to the undamped waves, so other apparatus had to be developed to receive them. Although various detector devices have been invented for this purpose, none have proved superior to the oscillating audion detector. This produces "beats" which are created by the use of properly designed inductances and condensers linked up to the audion circuit.

One of the latest receivers for undamped waves which employs the audion as a generator of "beats" is herewith illustrated. A large loose coupler is seen resting on top of the cabinet. The case contains four variable condensers which are provided with long insulating handles, the pointers of which move across the dials on the face of the instrument, as perceived in the illustration. The purpose of these handles is to prevent capacity effects due to the operator's body. The cabinet also contains the necessary inductances, the values of which can be changed by means of the jack and plug system; the jacks being located on the front of the board, as can be clearly seen in the illustration.

With the loose coupler herewith shown in connection with the variable condensers, wave lengths up to 15,000 meters can be readily obtained.

New Loose Coupler and Variable Condenser Cabinet Known as an "Undamped Waver," and Intended Especially for Receiving Continuous Wave Signals.



OVER-ALL EFFICIENCY IN RADIO TRANSMITTING STATIONS.

Several very vital figures are given in Dr. J. A. Fleming's new treatise, entitled "The Wireless Telegraphist's Pocket Book." We reproduce herewith an interesting chart as there given, covering the various losses in the apparatus constituting a typical transmitting set of the spark gap type. It is pointed out in the treatment of this subject to Dr. Fleming that, while these values as here reiterated are of considerable value as an over-all consideration, in respect to the over-all efficiency of modern transmitting sets, utilizing quenched spark gaps, etc., it may be a great deal higher. In comparing the power radiated, viz., 78 watts, with the power given to the step-up transformer, i. e., 800 watts, it is seen that for this particular transmitter the over-all efficiency is but 10 per cent., approximately. In the case of a well-designed spark transmitter the over-all efficiency might be raised to from 20 to 25 per cent.; that is to say, that almost one-quarter of the power given to the step-up or exciting transformer would be radiated as electric waves. Claims have been made for much higher efficiency in such apparatus, particularly for quenched spark sets when this value has been mentioned as reaching 75 per cent., but these claims have not been substantiated. This acknowledged authority points out that it is probably correct to say that the properly designed quenched spark transmitter's efficiency *may* reach a figure of 50 per cent.

He believes that it will not be far wrong to consider that in a fairly good, modern type spark transmitter, with quenched spark gap or gap equipped with an air blast, the power radiated from the antenna can be as much as 20 or 25 per cent. of that given to the exciting transformer, but it is not usual to find such high values as these. In order to realize such radio transmitter efficiency, however, great attention must be paid to the construction details of the condensers and also to those of the primary oscillation circuit and of the spark gap, as well as to the earth connection proper and to the construction of the antenna, in order to avoid undue resistance losses in these most vital parts of such a station.

EFFICIENCY CHART FOR U. C. L. RADIOTELEGRAPHIC EXPERIMENTAL PLANT, WITH 5 mm. SPARK GAP

(From tests by Dr. J. A. Fleming, at University College, London.)

The Evolution of Wireless Telegraphy

THE evolution of signaling without wires has been an interesting one. Since the earliest dawn of reason man has found it absolutely necessary to transmit important intelligence through space. Particularly in case of war between the various tribes quick intercommunication was desirable. As the fleetest runner, as well as the speediest rider, were soon found wanting, methods were naturally sought to outdistance both. In the illustrations here observed we have endeavored to show the principal modes of signaling without wires utilized in the various stages of the world's history.

Perhaps one of the first mentions is made in the Bible, when the Israelites were led out of Egypt and through the wilderness by a cloud of smoke by day and a pillar of fire by night. Possibly one of the first methods of signaling across an appreciable distance of a few miles was that involving the use of fires kindled on the hilltops or other promontories as depicted in Fig. 1. In this way it was quite possible to communicate intelligence accurately, although not very rapidly, to be sure. This scheme was first used in very ancient times.

The method of signaling shown at Fig. 2 is that employed at quite an early date, but notably by the North American Indians. This consisted in building a fire on a hill or mountain whenever possible, so that a column of smoke or a series of smoke puffs, could be sent up, and in this way communication was established between tribes. It was this method that was often utilized by the Indians when making war on the white settlers in America. The fire was made to smoulder by the use of wet sticks or leaves. The Indians were quite proficient in making fires producing a prodigious amount of smoke, which could be seen for various distances, depending, of course, upon the height of the hill upon which the fire was built, but a range of ten to fifteen miles was undoubtedly common in those days with this method of wireless communication.

Fig. 3 illustrates a little known yet very effective method of transmitting intelligence, which is attributed to certain tribes of Indians in South America; it has been described by returning explorers at different times. It may be expressed briefly as "drum beating," but the drum is no ordinary one. It consists of a hollow log, or a log made so by burning out the interior. Over the end of same is stretched the hide of an animal, which is pulled very tightly and bound by thongs. The log is then suspended, as perceived in the illustration, so as to exert the maximum resonating effect as the signaler beats the head of of the drum with a stick provided with a wooden head, or in some cases with a stick having at its extremity a ball formed from a piece of hide and loaded with a round stone. We have been credibly informed that this method is in successful use at present, messages being actually transmitted (using relay stations) over a distance of 300 miles almost every day.

Wigwagging is still in use to a great extent throughout the world, especially in the army and navy, where it has proved invaluable in many instances. This mode of signaling, which usually consists of wagging a flag or semaphore arm in different positions, representing the various letters of the alphabet, was employed at quite an early date. The illustration at Fig. 4 shows the semaphore arm as made use of for sending such signals over great distances. In the wonderful campaign of Napoleon carried out through France, Germany and Russia numerous messages were transmitted without wires in this way. In one case, it is said, that such a message was transmitted in a few hours' time from Moscow to Paris. Of course, this distance was not negotiated by one semaphore only, but the message was relayed from signal station to signal station, much in the same way as wireless messages are relayed now from ship to ship or from one ship to another and thence to shore, etc.

It is quite surprising how well sounds are carried through the earth itself, especially in rocky soil. Signals were transmitted in this way at quite an early date. At Fig. 5 the Indians are seen making use of this method of intercommunication. The scout, for instance, tapped a rock, partially buried in the ground, with another stone. At a surprisingly long distance away this sound could be heard by the Indians, whose hearing was extremely sensitive, by placing the ear to the rocky ground. Times without number the approach of men on horseback was heard in this way by the Indians, so that it was often very difficult for the United States troopers to conduct anything like regular warfare, as the savages would hear them coming several miles away and thus be able to circumnavigate them, or get to some little known hiding place.

A mode of signaling known to most of us, but one which dates back to the days of the first locomotive, is that making use of several distinct blasts of the steam whistle as portrayed in Fig. 6. Engineers to-day use this scheme for calling train crews and also for communication with other trains. One, two and three blasts of the whistle have different meanings assigned to them, etc. Locomotive whistles are often used for a signal of distress when the engine happens to be located near a large fire or when a wreck has occurred. In the latter case the whistle is usually tied down, so as to blow steadily until help comes, but at other times it is intermittently tooted.

Signaling wirelessly by means of a reflected ray of sunlight, is illustrated at Fig. 7. This method makes use of an instrument known as the Heliograph. It has been adopted by practically all army signal corps. This arrangement may be utilized without the aid of sunlight, wherever a sufficiently strong source of illumination is available, such as that produced by acetylene or electric light. Some of the army searchlights now built are provided with a shutter arrangement, similar to that fitted on the heliograph, so that long and short flashes of light may be sent out corresponding to the dots and dashes of the Morse telegraph code. Rapid signaling is thus accomplished, as it is possible to manipulate the heliograph shutter as speedily as the common telegraph key and sounder. A probable range for such devices as this may be put down as three to four miles ordinarily, but in most cases it is used for establishing communication between different signal squads or army posts at shorter distances. Signaling by this method can, of course, be carried on over a considerable range, and the more powerful the searchlight or other source of illumination utilized the greater the range.

We come now to the final method of signaling covered by this article on the evolution of wireless telegraphy, which is indicated at Fig. 8. As is well known, for this method of intercommunication there is invariably utilized a large size antenna or aerial, consisting of a number of wires supported by highly elevated masts. The illustration herewith shows roughly the appearance of the trans-Atlantic wireless telegraph station of the Marconi company located at Wellfleet, Mass. This method of signaling without wires has entirely transcended the dreams of wireless telegraphy entertained vaguely by the great scientists and engineers of even two decades ago. Wireless telegraphy in a practical sense and for commercial requirements has only been a reality since the year 1900, but to-day it has been developed to such an extent, involving the use of very high powered stations, that wireless messages may readily be propagated over such distances as 5,000 miles. This is mentioned to show what has been really accomplished, but this is freak work. Generally speaking, common ranges for moderate long distance radio telegraphy is 2,500 to 3,000 miles. There are a few stations working over such distances as 4,000 miles. Marvelous indeed has been the onward and triumphant march of science in the realm of intelligence transmission. Where and when will these wonders of science stop?

VIA "SAYVILLE" TO BERLIN.

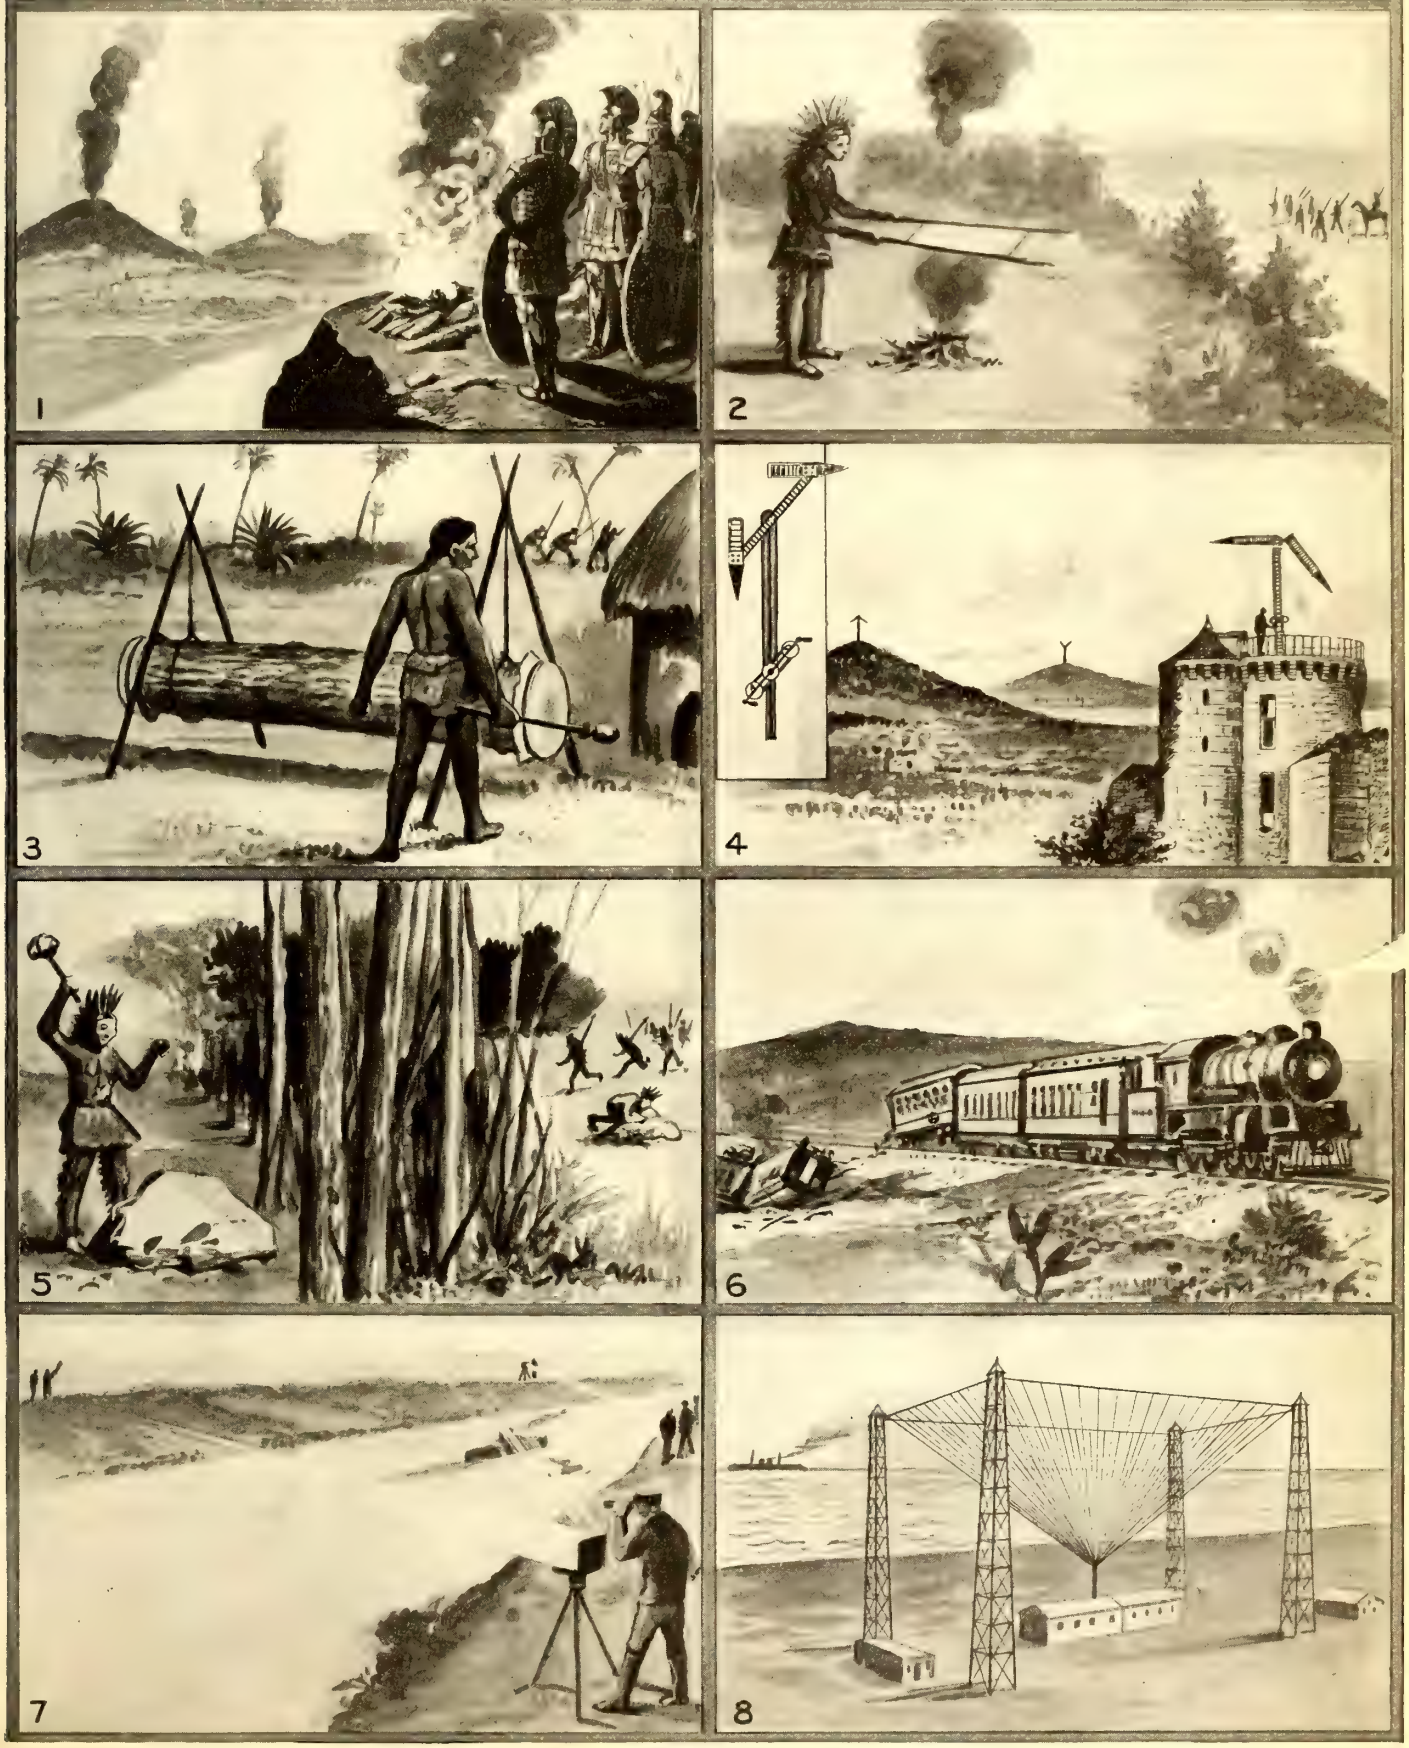
The Telefunken station at Sayville, L. I., is one of the most powerful in the world, flashing messages nearly 4,000 miles direct to Nauen, near Berlin.

Located near the ocean and dropped in a mosquito-infested field, the great Telefunken station sprawls over 100 acres. A mile away it looks like a huge spider web, with all its slim poles reaching into the air, interlaced with slender wires. At the gate a watchman is on guard, and all along the way to the building are posted danger signs.

The little low building is rigged on every side with towering poles—antennae as they are called. Five hundred feet high they stand—almost as tall as the Washington monument. From these wires radiate the electric waves that leap across space to Germany. Great blocks of cement, big as corncribs, are set in the ground and to them are anchored the guywires.

Inside the low, one-story building, squatting at the foot of the towers, are 18 men working. Fourteen of these are censors for the United States Government, as for several months the navy has been in control of the Sayville station. Every message must be sent through them and received through them. The Telefunken employes operate the plant, but all messages have to be submitted to the Government censors.

The message is flashed across the Atlantic at the rate of 25 words a minute, but in case of necessity it can go up to 40. The messages go to a small town near Berlin called Nauen, where they are placed on a land wire and forwarded to the capital. The charge for sending a message to Germany is 53 cents a word from anywhere near New York. The 3 cents is the price of the land wire to get it to Sayville.



As soon as the key is touched in America the message is in Germany, the time occupied in crossing being only the fraction of a second. In fact, the message could go around the world seven times in a second.

Every message is censored before it goes out. A Government officer sits there with a blue pencil and if he suspects the message has another meaning than what is on its face he returns it to the sender; or he may paraphrase its meaning, saying the same thing in different words, which would of course upset the code message, if it contained one.

On an average 100 messages a day go out of Sayville for Berlin. Most of these

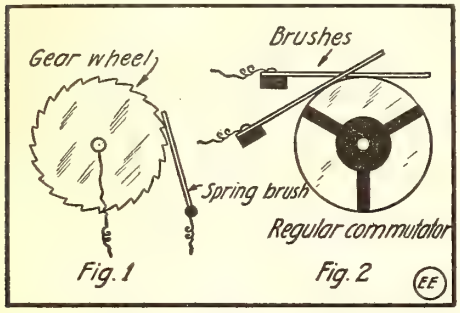
THE EVOLUTION OF WIRELESS TELEGRAPHY



For Explanatory Text, See Preceding Page.

The Reception of Long Damped and Undamped Waves*

By Thomas Appleby

ALTHOUGH it is not generally known there are at least three stations in this section of the country (Philadelphia, Pa.) now using undamped waves for transmission. Two of these stations generate the undamped waves with the oscillating arc; while the third makes use of a high frequency generator.

Figs. 1 and 2. Two Forms of "Tikker" for Receiving Undamped Waves.

In the ordinary spark station two frequencies are used, one being the radio frequency which determines the wave length and the other the audio frequency which is produced by the rotary or quenched spark gap, and this determines the pitch of the spark as heard at the receiving station.

In an undamped wave transmitting station there should be no audio or spark frequency, as the oscillations which determine the wave length are generated by a high frequency generator of 50,000 cycles or more, or by an oscillating arc which is more or less silent in operation.

When an undamped wave is tuned in at the receiving station and an ordinary crystal detector used there should be no sound in the telephone receivers, as the radio frequency is entirely too high for the human ear. There are exceptions, however, for we can plainly hear the Tuckerton station with a crystal detector, even though they use the high frequency generator; and not only do we hear the actual sending, but we can also hear the reversed sending caused by the compensating wave, due to the manner in which the key is shunted around a few turns of the helix. However, the signals received in this manner are very faint, compared to the great strength of the signals when a tikker is used.

In order to lower the frequency of the current set up by the undamped waves; or, in other words, to produce an audible frequency, it is necessary to break up the incoming current at the receiving station.

This may be accomplished in two ways: First, by the use of a tikker, which consists in its simplest form of a rotating gear wheel with a spring held against the teeth; the pitch of the signal being determined by the speed of the tikker wheel (Fig. 1).

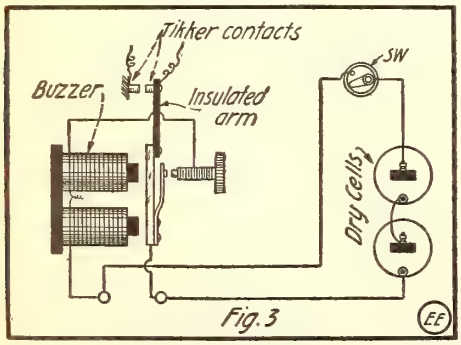


Fig. 3. "Tikker" Made Out of Ordinary Buzzer.

Another form of tikker would consist of a revolving commutator, such as is used on small motors, with two copper brushes bearing on the sections and arranged so that the circuit is constantly made and broken by the passing sections of the commutator (Fig. 2). The absence of noise in this form of tikker makes it more desirable than the first. An ordinary electric buzzer may be provided with an extra set of contacts well insulated from the buzzer itself and used as a ticker (Fig. 3). All of these break up the incoming signals into a lower or audible number of vibrations, which can be easily heard in the receivers.

It is not absolutely necessary to use a crystal detector along with the tikker, but is advisable, as the signals come in much louder.

The circuits for use with the tikker and detector are similar to the ordinary receiving circuits. The tikker may be connected in various places in the detector circuit with nearly equal results. It operates satisfactorily when in series with the detector, in series with the 'phones, across the stopping condenser, across the variable condenser, or even shunted around the secondary coil.

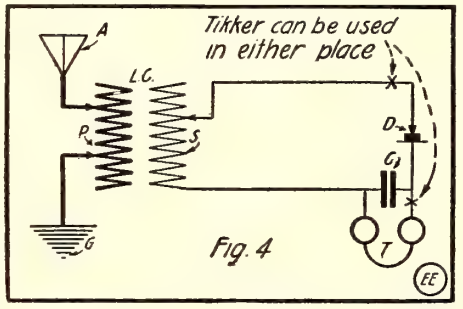

Fig. 4. Hook-Up for Poulsen "Tikker" in Receiving Circuit.

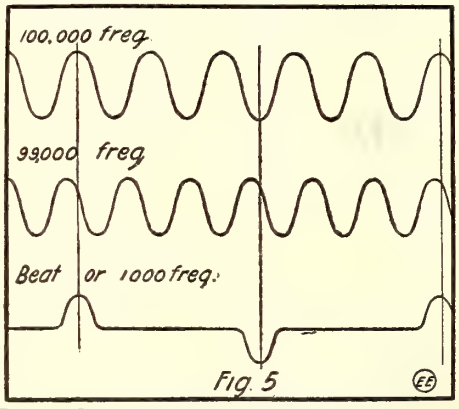

Fig. 5. Demonstrating How "Beats" Are Produced by Two Slightly Differing Oscillators in a Common Circuit.

The second method of lowering the undamped wave frequency is by means of the heterodyne effect, as discovered by Prof. R. A. Fessenden.

When two piano strings are tuned to slightly different tones, a third tone, or "beat," as it is called, will be heard. The piano tuner does not listen to the tone of the strings when tuning a piano, but listens for the "beats," which occur when the two strings are slightly out of tune. The nearer the two strings approach the same tone, the slower or lower the beats become. When the strings are considerably out of tune, the beats are very rapid and produce a high tone of their own.

In much the same manner we produce "beats" in the receiving circuit. The production of these "beats" is called the heterodyne effect. We set up oscillations in the receiving circuit which are slightly different in number than those of the incoming wave. The result is "beats," and the nearer we make our frequency to the incoming frequency the lower we will make the tone of our "beats." If the incoming frequency is 100,000 per second, and we generate 99,000 oscillations per second in our receiving circuit; the difference between the two, or 1,000, would be the frequency or tone of the beats (see Fig. 5). This would sound like the whistle of 1,000 sparks per second, as produced by the 500-cycle quenched gap.

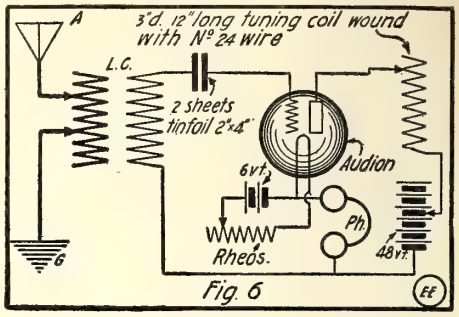

Fig. 6. Oscillating Audion Circuits.

Oscillations may be set up in the receiving circuit by means of a near-by oscillating arc, or by use of an oscillating audion as used in the ultraaudion or Armstrong circuits (see Figs. 6 and 7).

Tuckerton station (W.G.G.) makes use of a high frequency alternator and sometimes the arc for generating undamped waves. Sayville now uses the oscillating arc and Arlington also uses the oscillating arc at times to work with NBA.

Tuckerton can be heard on about 8,500 meters wave length; Sayville is on about 9,000, and Arlington on about 5,000 to 7,000 meters, considering undamped waves.

Tuckerton and Sayville work between 7 p. m. and 2 to 3 a. m.; as a rule, they work for about one hour each, Tuckerton shutting down while Sayville is working, and vice versa. Arlington transmits at times during the evening, and often during the day time.

We have received all these stations on our 300-foot, two wire aerial, in West Philadelphia, although at present we only use half of this length, or 150 feet. The loading coil in series with an ordinary loose coupler consists of a tube four inches in diameter and 12 inches long, wound with No. 24 B. & S. enameled wire. A 43 plate variable condenser is shunted around both the loading and loose coupler primary coil. In the detector circuit we use a 43 plate variable condenser across the secondary which is wound with No. 30 B. & S. silk-covered wire. We found, however, that the 43 plate condenser was unnecessary in the detector circuit and when removed the signals could be tuned in just as strong, pro-

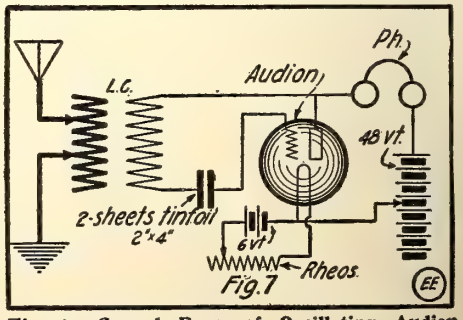

Fig. 7. Second Form of Oscillating Audion Circuit.

*Paper presented before the Wireless Association of Pennsylvania, Sept. 24, 1915.

vided tight coupling was used. Of course we do not receive efficiently with this arrangement, as the aerial is not balanced for these waves, but simply oscillates, due to

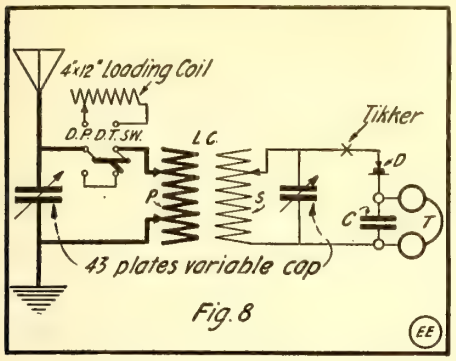

Fig. 8. Hook-Up for Reception of Undamped Waves with "Tikker," Including Loading Coil Cut-Out Switch.

forced oscillations, and sets the loading coil loose coupler primary coil and shunted condenser circuit (which is actually tuned to the desired wave length) oscillating. The detector circuit also probably oscillates, due to forced oscillations from the primary circuit (see Fig. 8).

We are now constructing the proper loading coils to load up all the circuits until we have resonance. The above arrangement is so simple and can be secured with such little additional apparatus that the average amateur will probably be inclined to give it a trial. The signals from Tuckerton, Sayville and Arlington are strong, but when resonance is secured they will be many times stronger.

We are also constructing some loading coils for use in receiving the foreign stations working on as high as 20,000 meters. Petrograd, Russia, is said to use 20,000 meter waves, as are some others. One of the new Marconi stations in New Jersey can be heard testing some evenings on 18,000 meters. They use an audio-frequency or spark system and the crystal detector is all that is necessary. A wireless authority in New York City, and another in Washington, claims that the 20,000-meter foreign stations can be easily received on a 150-foot amateur aerial, and to the experimenter who has tired of listening to the ordinary short wave stations the writer would advise that he get busy and tune in the long wave stations, especially the undamped waves.

THE GROUND LEAD AND ITS PROPER USE

By Electron.

Not one radio amateur in a hundred is

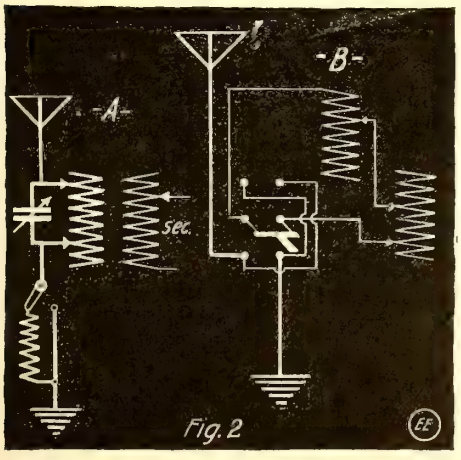

Fig. 2. Diagram of Ground Switch Change-Over for Radio Receiving Set.

aware of the possibilities of increasing his range that lie in his ground lead. It may be properly insulated and grounded, yet they overlook the benefits that may result from a little time and energy spent in making the few changes suggested in these short paragraphs.

First we will consider its length; the shorter it is the higher the amperage that is induced in the secondary circuit, and, correspondingly, the longer it is—within a certain limit—the higher the voltage in the secondary circuit.

Just why this is will be apparent by glancing at Fig. 1, which shows roughly diagrammatically the voltage and amperage characteristics in the open aerial circuit. We will consider a vertical aerial set into oscillation by an incoming wave. When this aerial is swinging in resonance with the incoming wave the induced voltage is greatest at the top and lowest at the bottom or ground connection. Hence, according to Ohm's law, the reverse is true of the current, which is lowest at the top of the aerial and maximum at the ground.

Going one step further, imagine the receiving set connected in at a point in the circuit indicated at A (Fig. 1). The cur-

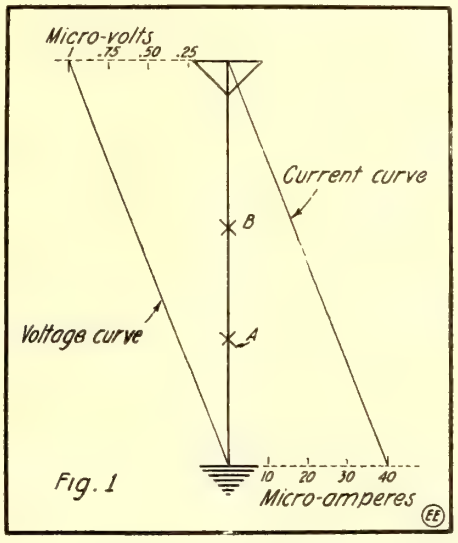

Fig. 1. Approximate Graphical Relation of Current and Voltage in Antenna.

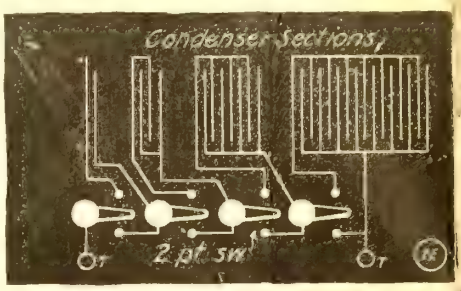
rent here has a comparatively large ampere value and a comparatively small voltage value, therefore amperage predominates in the energy induced in the detector circuit. This condition is best for detectors acting on the thermo-electric principle, such as galena, and the signals will of course be comparatively loud.

The opposite tends to be the case when the set is connected at a point in the circuit indicated at B. Here the voltage predominates and the voltage in the detector circuit will be higher than in the previous case. These conditions are ideal for sets utilizing the audion, for instance.

The above explains the theory, and now we will consider the application of these effects to practise. It is practically impossible to change the connections as mentioned in the foregoing, but two alternatives remain.



One method (A) that can be utilized to good effect is to install two ground leads, with a switch to change from one to the other. One of these leads should run as straight as possible to the ground connection and the other should possess an inductance, which may consist of about 75 turns of No. 24 C. C. magnet wire wound on a core 4 inches in diameter.

The other method (B) is to install a D. P. D. T. switch to enable one to throw the load coil from the aerial to the ground lead. It is understood if you only use mineral detectors it is unnecessary to have two leads, and if audions are used exclusively connect the load coil in the ground lead permanently.

The diagrams appended show the connections of the switches for the use of those who use both the audion and mineral detectors as receptors.

A SIMPLE VARIABLE CONDENSER SWITCH.

The following is the description of a variable condenser switch which will work on either sending or receiving types. The

Unique Switching Scheme for Adjustable Condenser.

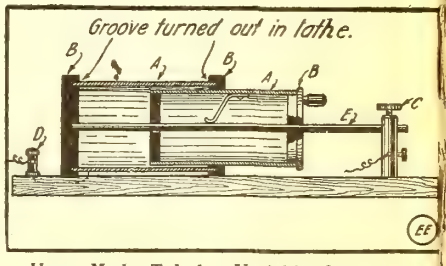
plates are arranged as shown in the diagram and are connected to four two-point switches. The condenser plates can be of tinfoil, separated by paraffin paper for receiving or put on glass with some shellac for sending types. The whole should be placed in a box, with the switches outside in any convenient place. One more two point switch and 32 more plates can be added and the capacity is doubled.

Care should be taken not to put all the switches to the right, as it will short-circuit the other instruments.

Contributed by C. J. FITCH.

A TUBULAR VARIABLE CONDENSER.

This condenser may be constructed almost entirely of parts to be found about the average amateur workshop. The dimensions may be varied to suit conditions but the author has found the following dimensions most satisfactory: Length of outer tube, 5½ inches; diameter of outer tube, 4 inches; length of inner tube, 5½ inches; diameter of inner tube, 3¾ inches.



A wire soldered to the bottom makes connection with the outer tube, while connection with the inner one is made by means of a slider of phosphor bronze which presses on the brass rod as shown in the illustration.

A layer of Empire cloth, or oiled linen is secured around the inner cylinder by a thin coating of shellac, or, better, beeswax.

The uprights are composed of oak and finished with shellac. The base is best made of slate. This instrument possesses great ease of adjustment, and there is no possibility of a short circuit.

THE CONSTRUCTOR

The Use and Construction of a Decremeter

By Milton B. Sleeper

WHILE most experimenters are familiar with the measurements commonly made in radio work, not many understand the measurement of "decrement." Since the sharpness of the radiated wave depends upon the decrement (or damping), this value must be measured if the tuning characteristics of a transmitter are to be predetermined or made known. To reduce the interference as far as possible, the law requires that the logarithmic decrement shall not exceed 0.2. Several kinds of decremeters* have been developed, but the one described here is the simplest. This type was first used by the Marconi Co.; the formula on which its operation depends is due to V. Bjerknes. The construction of the instrument will first be taken up; then its use.

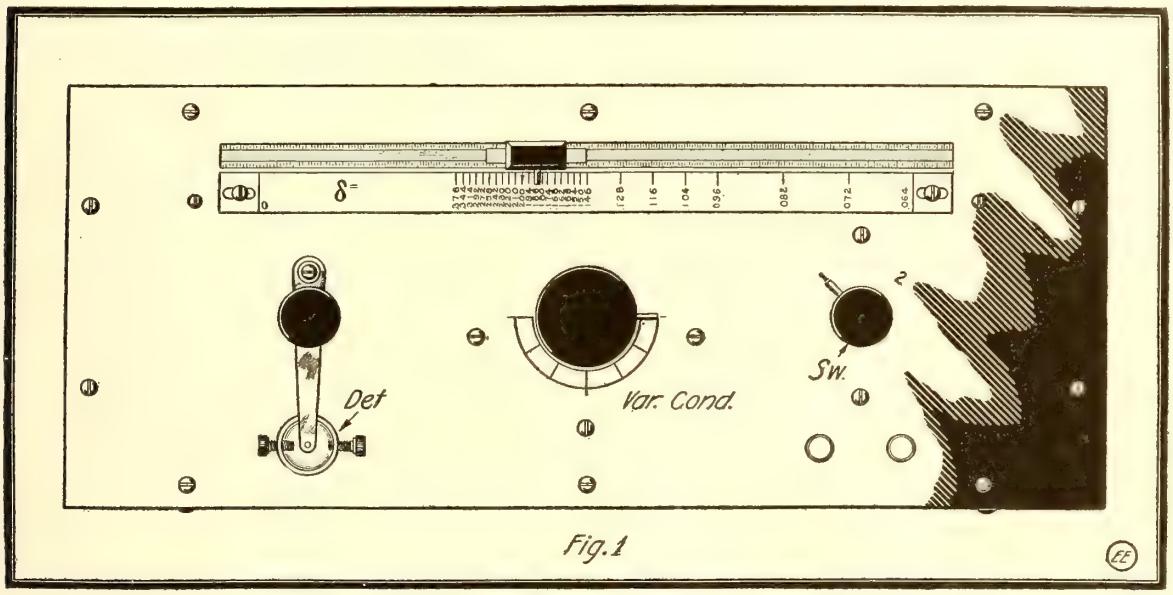

Fig. 1. Front View of Finished Decremeter.

Construction of the Decremeter.

Fig. 1 shows the front of the instrument, while Fig. 2 gives the connections. At the left of the front view is the detector. Any mineral is suitable if it holds its adjustment well. The handle in the center is for the variable condenser. At the right is the switch, represented in the diagram of connections by the numbers 1, 2, 3, 4, 5, 6. Below the switch are binding posts for connecting any suitable 'phones. Across the top is arranged a slider which projects through the slot in the hard-rubber front. The damping decrement can be read directly from the scale. If it is desired the decremeter can be calibrated at the Bureau of Standards, Washington, D. C., but if the decremeter is carefully constructed it will be accurate enough for all purposes. Although it is far better to keep all the parts inclosed, this instrument will work as well if the essential parts are made according to the drawings, but mounted on a plain base.

The Variable Condenser.

The condenser is of the rotary type and of about .0005 mfds. capacity. It is much better in most cases to buy a condenser than to make one. However, the home-made one described here will be satisfactory if the instructions are closely followed. A list of parts is given to help the builder in getting the material ready. From perfectly flat No. 25 gauge aluminum sheet, cut out 10 pieces 2½x1½ inches. These are for the rotary plates. On two mark out the shape of the plates as shown by 17 in Fig. 3. Clamp the stack of plates between two blocks of wood the marked pieces on the outside. Using these as a guide, cut along the lines with a fine hand jig-saw, well lubricated with kerosene. Drill the holes for the shaft, too, while the plates are still clamped. From rectangles 3x1½ inches cut out the nine thin stationary plates and the two thick ones, acccording to the drawings. Drill the holes around the edges, but

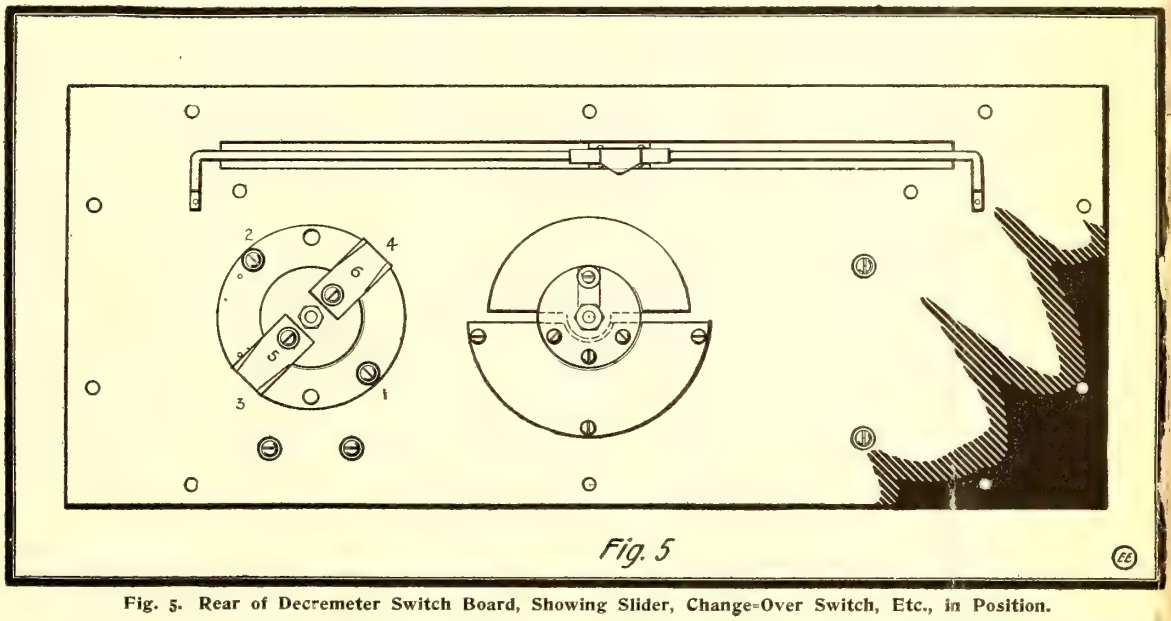

Fig. 5. Rear of Decremeter Switch Board, Showing Slider, Change-Over Switch, Etc., in Position.

*This decremeter was actually built and checked against a standard instrument. With a little care a faithful duplicate can be constructed. —EDITOR.

do not drill the holes for the bearings in the thick plates. If there are any burrs on the plates, rub them off with emery cloth. Washers can usually be purchased. They must be between 0.063 and 0.062 inches in thickness. Test each one with a micrometer. In drilling the bearings, 14 and 15, clamp them to the thick plates and drill the holes in all of them at the same time; otherwise the bearings will not be in alignment, and the plates will touch. Now tap the holes for the screws, 7, which hold the bearings to the thick plates.

When the stationary plates are finished to the front of the case. The threaded washers, 9, are to hold the rotary plates in position on the shaft. To make sure that both sets of plates have been tightened up the same amount, try the edges of the assembled rotary plates against the assembled stationary ones. Finally, slip the rotary plates between the stationary ones, put the bearings on the shaft, and screw them down in place. When it is time to put the condenser on the hard-rubber front bend the spring, 1, to a bow shape. It belongs on the shaft between the front and the handle. This spring, pressing against the handle, will hold the plates in any position. The nuts, 6, hold the plates from being pulled out of alignment by the spring. In the side view of the assembled instrument, Fig. 4, the complete condenser is clearly shown. The connecting wires have been omitted to make the drawing clearer. Fig. 5 shows the condenser in position on the back of the hard-rubber front. The connection wires are left out in this drawing also.

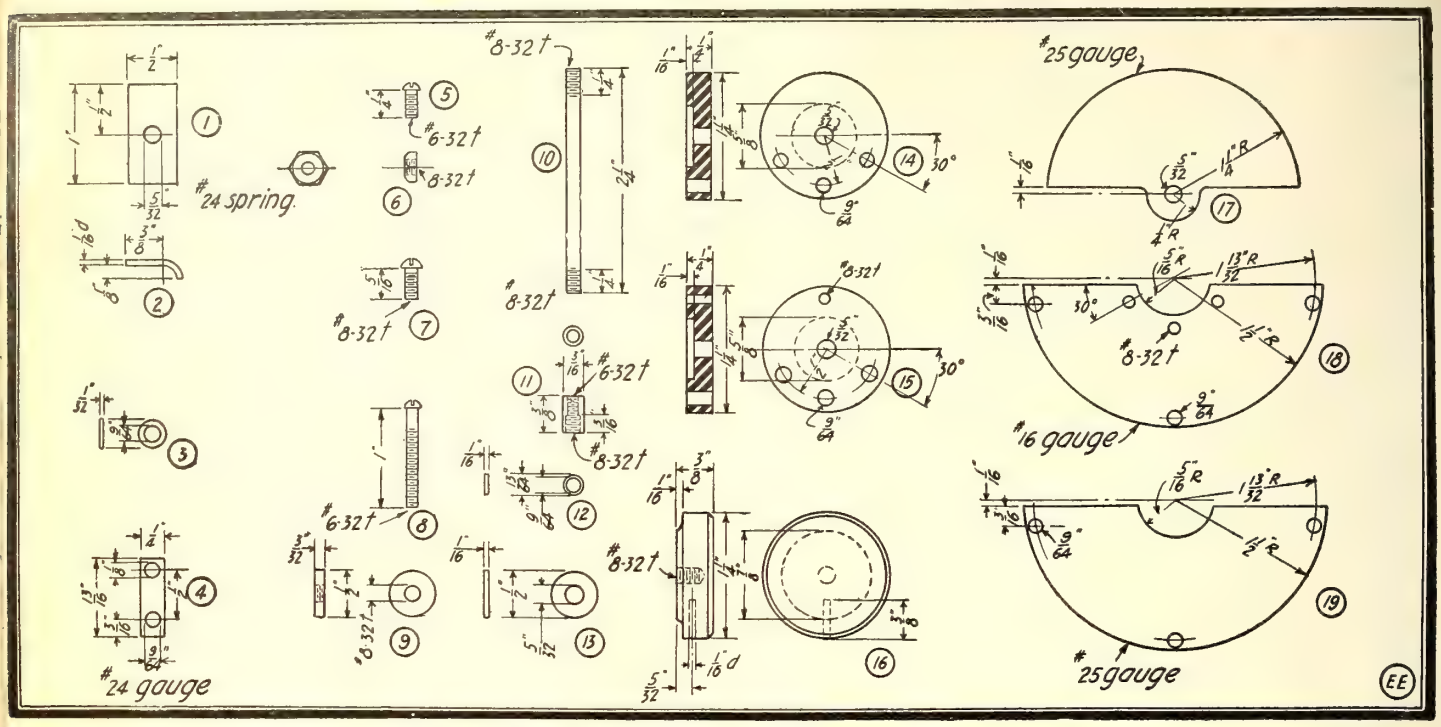

Fig. 3. Details of Decremeter Variable Condenser Parts.

assemble them on the screws, 8. The ends of the pieces 11, which have the smaller holes, go on the screws 8 to keep the plates right; the ends with the larger holes are for the screws 7, which hold the condenser

The Inductance Coils.

The inductance coils and contact slider are depicted in detail in Fig. 6. Wind the long coil, 32, with No. 22 double cotton covered copper wire. By soldering a piece of copper foil to the bared wire take taps at the 26th and 52d turns. Wind the smaller coil with 26 turns of No. 22 double cotton covered copper wire. The completed coils are shown in Fig. 4 as they appear when held in place by the straps 40.

Be very careful in laying out the scale 45. Divide the 8-inch space into 100 equal parts.

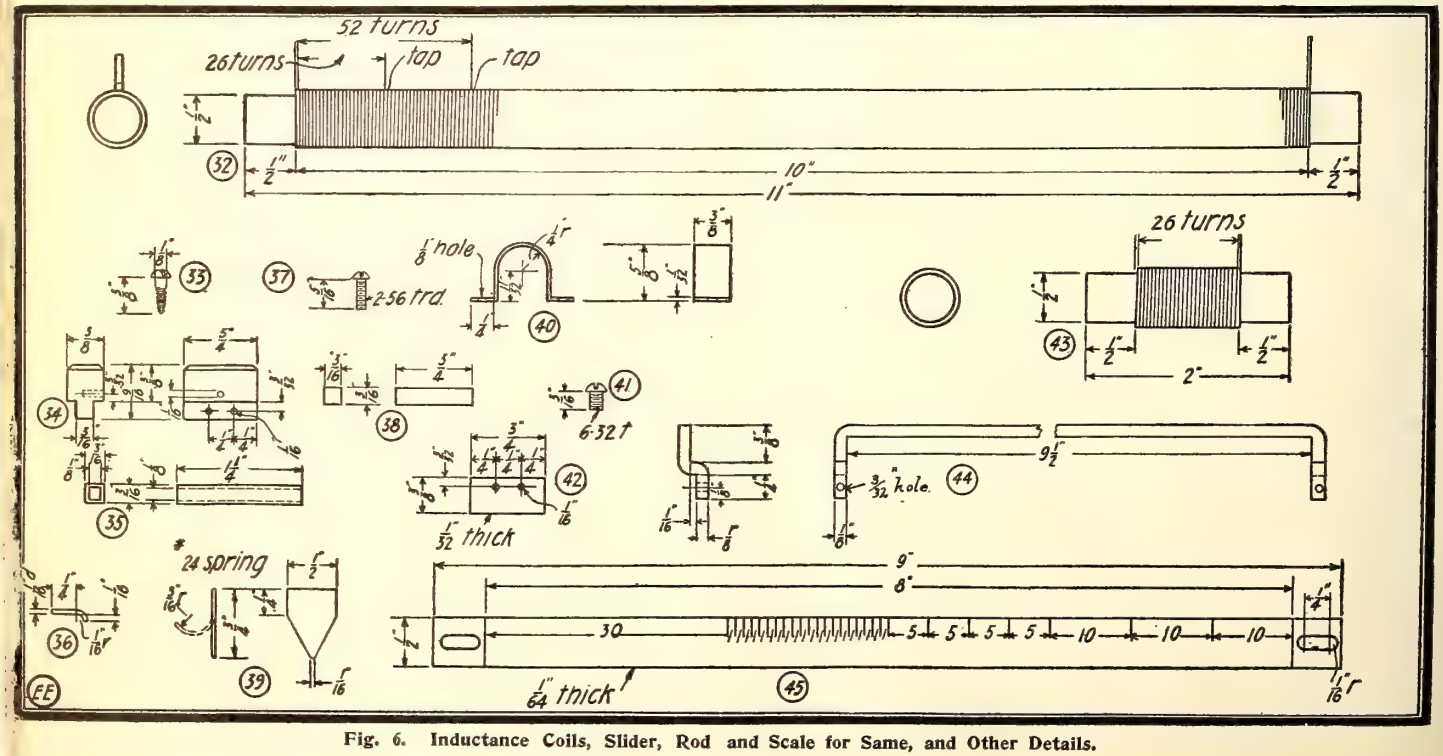

Fig. 6. Inductance Coils, Slider, Rod and Scale for Same, and Other Details.

Then make the divisions for the *decrement readings* as given in the table below:

Number of Graduation Marks on the Scale with Decrement Readings.

Scale.	Decrement.	Scale.	Decrement.	Scale.	Decrement.
30	0.378	40	*0.200	49	0.150
31	0.344	41	0.194	50	0.146
32	0.314	42	0.186	55	0.128
33	0.292	43	0.180	60	0.116
34	0.272	44	0.174	65	0.104
35	0.258	45	0.168	70	0.096
36	0.242	46	0.162	80	0.082
37	0.230	47	0.158	90	0.072
38	0.220	48	0.154	100	0.064
39	0.210				

*Legal limit.

When the scale is in position on the hard-rubber front move it until the pointer is on the zero mark, when the slider contact is on the 26th turn of the larger inductance. This must be done carefully if the meter is to be accurate.

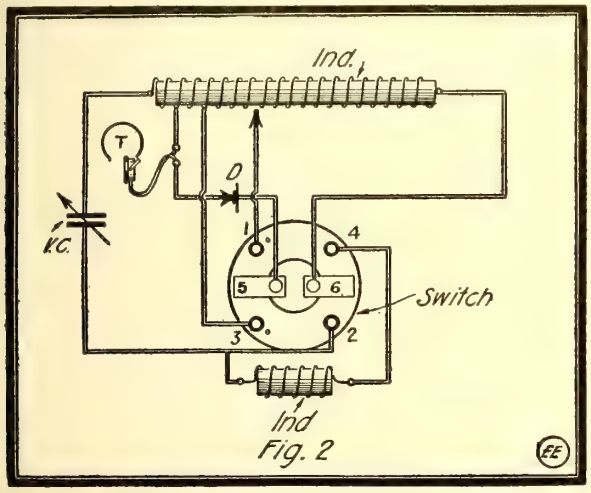

Fig. 2. Wiring Diagram for Parts of Decremeter.

This makes a place for the narrow part of the slider handle, 34, to fit in. Solder the contact, 39, to the bottom of the tube. Now fasten the handle to the slider by means of escutcheon pins or small rivets, put through the holes in the handle and the side pieces 42. Fit the pointer, 36, tightly in the hole of the handle. Be sure to put the completed slider on the rod, 44, before bending the rod in the shape indicated by the drawing. Make sure, also, that the contact is on the right side of the rod. These parts finished, we may start constructing the change-over switch.

[In the second part of this paper on the construction of a decremeter Mr. Sleeper explains how to use same for measuring wave length, decrement, etc. Don't miss it!—Ed.]

WAVE LENGTH AND DAMPING.

It is a little known fact that the Government pays little or no attention to a highly damped wave under 200 meters, whereas it reprimands and punishes amateurs who use a wave length in excess of 200 meters. Select the lesser evil to avoid fines. However, for maximum range the decrement should be kept down.

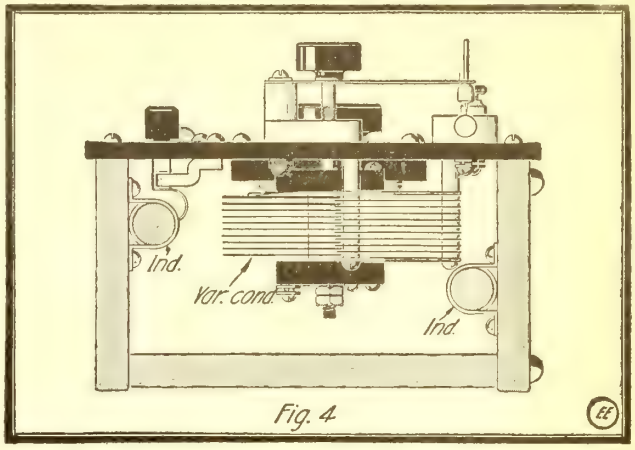

Fig. 4. End View of Decremeter with Cabinet Board Removed.

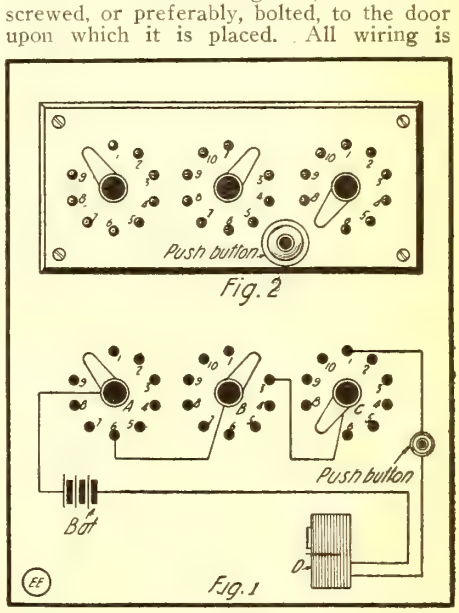
LIST OF PARTS.

Drawing Number	Name of Part	Size	Pieces	Material
1	Spring to go on shaft under handle	1″x ½″x 24 gauge	1	Spring brass
2	Pointer for handle	9/16″x 1/16″ diam.	1	Brass
3	Washers to hold connection wires	1/32″x 5/16″ diam. 9/64 hole	2	Brass
4	Connection piece for bearing	13/16″x ¼″x 24 gauge	1	Brass
5	Screw for making connection to No. 4	¼″, 6-32 thread	1	Brass
6	Nuts to adjust plates	8-32 thread	2	Brass
7	Screws to fasten bearings to outside plates	5/16″, 8-32 thread	6	Brass
7	Screws to fasten No. 11 to front of case	5/16″, 8-32 thread	3	Brass
8	Screws to hold stationary plates together; goes in No. 11	1″, 6-32 thread	3	Brass
9	Washers to hold rotary plates	3/32″x ½″ diam. 8-32 T	2	Brass
10	Shaft for rotary plates	2¼″, 8-32 thread	1	Brass
11	Pieces to hold stationary plates to front	⅜″x 3/16″ diam. 8-32 and 6-32 thread	3	Brass
12	Separators for fixed plates	1/16″x13/64″ diam. 9/64″hole	30	Brass
13	Separators for rotary plates	1/16″x½″ diam. 5/32″ hole	9	Brass
14	Bearing nearer front of case	¼″x 1¼″ diam.	1	Hard rubber
15	Bearing at back	¼″x 1¼″ diam.	1	Hard rubber
16	Handle	⅜″x 1¼″ diam.	1	Hard rubber
17	Rotary plates	25 gauge, 2½″ diam.	10	Aluminum
18	Outside stationary plates; fasten bearings to them	16 gauge, 3″ diam.	2	Aluminum
19	Inside stationary plates	25 gauge, 3″ diam.	9	Aluminum
20	Nuts to screw on either side of No. 30	8-32 thread	2	Brass
21	Pointer for handle	⅝″x 1/16″ diam.	1	Brass
22	Switch contacts	1″x ½″, 24 gauge	2	Spring brass
23	Spring to go under handle	1″x½″, 24 gauge	1	Spring brass
24	Washers for connections	1/32″x5/16″ diam. 5-32″ hole	12	Brass
25	Pins to stop contacts	⅜″x 1/16″ diam.	2	Brass
26	Screws to hold No. 31 to front of case	⅜″, 8-32 thread	2	Brass, round head
27	Screws to hold connections	¼″, 8-32 thread	6	Brass, round head
28	Shaft	1″, 8-32 thread	1	Brass
29	Handle	⅜″x ¾″ diam.	1	Hard rubber
30	Movable contact holder	⅜″x 1¼″ diam.	1	Hard rubber
31	Stationary contact holder	¼″x 2 5/16″ diam.	1	Hard rubber
32	Core for large coil	11″x ½″ diam.	1	Well-seasoned wood
33	Screws to fasten coil holders to case	⅜″x⅛″ diam.	8	Brass
34	Handle of slider	¾″x 9/16″x ⅜″	1	Hard rubber
35	Tube for slider	1¼″x⅛″ sq. i.d. 3/16″ sq. o.d.	1	Brass
36	Pointer for slider handle	⅜″x 1/16″ diam.	1	Brass
37	Screws to fasten slider rod to front of case	5/16″, 2-56 thread	2	Brass, round head
38	Support for slider handle	¾″x 3/16″x 3/16″	1	Brass
39	Contact for slider	¾″x ½″, 24 gauge	1	Spring brass
40	Coil holders	2″x ⅜″x 1/32″	4	Brass
41	Screws to hold scale to front of case	3/16″, 6-32 thread	2	Brass, round head
42	Pieces to hold slider handle	¾″x ⅜″x 1/32″	2	Brass
43	Core for small coil	2″x ½″ diam.	1	Seasoned wood
44	Slider rod	11″x⅛″x⅛″	1	Brass
45	Scale	9″x ½″x 1/64″	1	Celluloid
46	Front of case	12¾″x 5½″x 3/16″	1	Hard rubber
47	Back of case	11¾″x 4½″x ⅜x ⅜″	1	Mahogany
48	Top and bottom of case	12⅝″x 2 11/16″x⅜″	2	Mahogany
49	Ends of case	2 10/16″x 4½″x⅜″	2	Mahogany

To assemble the slider, first solder the piece 38 on the middle of the tube 35. To opposite sides of 38 solder the pieces 42.



AN ELECTRIC COMBINATION LOCK.

A secret electrical lock is frequently desired on cupboards, little closets and shop doors to keep out undesirable parties. The common method of opening these locks is to use secret contacts, such as two nails, the circuit being closed by a coin or piece of metal.

The lock herewith described has many of the advantages of the above, but is in the form of a combination and can be opened by no one save those who know the prearranged setting of the lock.

The materials needed are 3 switch levers, 30 contact points, 1 push button, 2 or 3 good dry cells and an electric door opener. The circuits and wiring diagram are shown in Fig. 1. A, B and C are the switch levers. Ten contacts are used per switch and arranged on a 1-inch board, 8½x4½ inches. After the levers and contacts are arranged the combination is to be decided upon and hooked up accordingly. In the illustration the combination is 6-3-1. It will be seen that unless switch lever A is on contact 6, switch lever B on contact 3 and switch lever C on contact 1, it will be impossible, upon pushing the button, to open the door upon which the electric lock D is fastened. A great variety of combinations can be had, it being possible to arrange 1,000 different settings with the scheme illustrated.

The appearance of the finished device will be as shown in Fig. 2. It should be screwed, or preferably, bolted, to the door upon which it is placed. All wiring is taken to the inside of the door to prevent anyone meddling with the circuits.

Handy Electric "Combination" Lock for Drawers, Tool Boxes, Etc.

Contributed by A. R. DARLING.

An Electro-Magic Skull

By Homer Vanderbilt

MOST readers of this journal are undoubtedly familiar with the "rapping skull" used by stage magicians, but are possibly doubtful as to how it really works. Several of these schemes

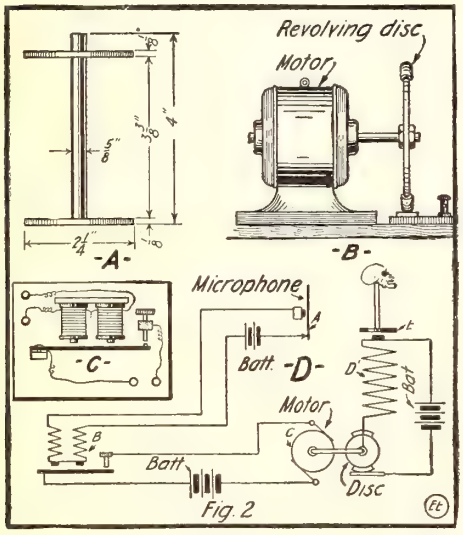


Fig. 2. Circuit Arrangement for the Mystic Skull.

have been developed by different workers in the field, and one of these is herewith described in detail.

The general principles upon which this trick works are as follows: A sensitive microphone, A (Fig. 1), of the *carbon ball type*, is connected in circuit with a relay, B (see also Fig. 2, D), and its armature circuit is linked with a motor, C, and battery. Upon the motor shaft a proper circuit breaker is placed and the latter is connected in series with a powerful electro-magnet, D^1, actuating an iron armature, E, which is connected to a rod, F, operating lever G, which is fastened to the (balanced) lower jaw of the skull, as perceived. Now, when you speak or produce any sounds near the instrument, the microphone will be disturbed, operating the relay, which will connect and work the motor, and in turn the circuit breaker. Consequently the electro-magnet D^1 is put in operation and the result is that the jaw is pulled up by the action of the rod F, actuated by the magnet. When the current is released the slightly overbalanced weight of the jaw will cause it to drop back. The arrangement herewith shown will only cause a double rap of the jaw, but the number of them may be varied by increasing the number of segments on the circuit breaker.

The writer will unfold the details of his apparatus and thereby the experimenter will be enabled to build such a device for amusing his friends. It is certainly very amusing to witness the astonishment of the visitors when the skull is operated.

The constructional details of the individual apparatus are shown in Fig. 2. The electro-magnet "A" is made to size, as perceived, and is fully wound with No. 22 B. & S. copper magnet wire. The circuit breaker "B" consists of a disc revolved by a motor and which makes contact with a brass strip located at the bottom of the base, as depicted. The relay "C" is made of two bell magnets actuating an iron armature carrying a contact point which coacts upon a second point, as seen. Connections for the various parts are shown in drawing "D." Practically any kind of relay can be advantageously used. The transmitter is of the supersensitive type and which can readily be made by following the instructions given in the November, 1915, issue of this journal on page 333 in an article entitled "How to Build a Dictaphone." After these various instruments are made they should be properly arranged as portrayed in Fig. 1 and connected as shown in "D," Fig. 2. The instrument is now ready to be used. The only thing necessary to operate the jaw of the skull is to talk or blow a whistle, which will affect the transmitter and in turn the jaw, thereby causing it to rap very mysteriously.

In conclusion several points may be mentioned which if followed will make the apparatus work and appear much more professional. Firstly, the contact disc had best be geared up to the motor, so that it makes about one revolution to 20 or more of the motor shaft. Again, the skull should be arranged so that it may be picked up from the stand and shown to the audience. At Fig. 3, "E," is indicated how a separable rod joint, X, may be contrived, enabling the operator to remove the skull easily for inspection. An indirect electrical method is the best way in which to actuate the jaw. At Fig. 3, "G," is perceived how the electro-magnet D may influence magnetically an iron disc, X_2, joined to the movable jaw, as usual, by a lever or wire. This

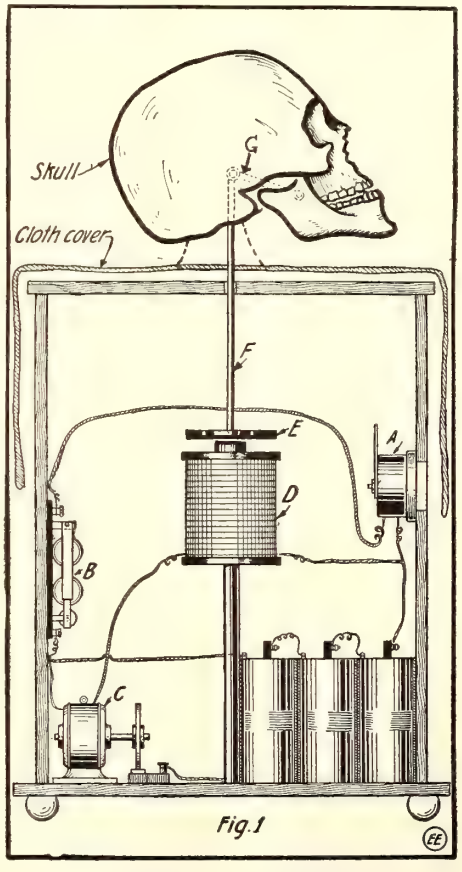

Fig. 1. Assembly Details of Mystic Skull in Cabinet.

permits of minute inspection by the audience. Again, the effect can be attained by placing an aluminum ring in the jaw (properly balancing the jaw to make it work easily) and an alternating current electro-magnet, by induction, will repel the ring (and hence the jaw also) whenever it is energized.

These latter schemes are merely suggestions that may be used to give the apparatus a professional appearance. A final word; it is absolutely necessary to mount the cabinet on a solid support, otherwise vibration will cause it to operate of its own

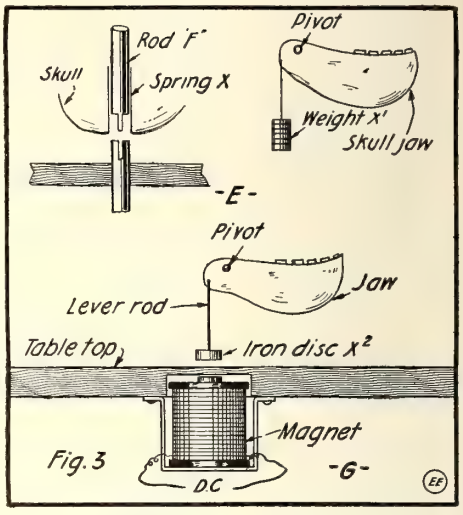

Fig. 3. Details of Jaw Actuating Mechanism.

accord and spoil the whole illusion.

VALUE OF RADIO TO VESSELS IN DISTRESS.

During the fiscal year 1915 the radio inspectors of the United States Navigation Bureau reported 26 cases of vessels leaving our ports which met with accident or disaster, requiring the use of wireless to summon assistance. Four of these were from fire; 12 were from running ashore, stranding, or getting into an ice jam; 3 were from the breakage of machinery; 4 resulted from collisions; 1 from shifting of cargo; 1 vessel was storm-battered and waterlogged; and 1 was torpedoed. Excepting in the case of the "Lusitania," which was torpedoed, the assistance thus rendered resulted in but two lives being lost. Since the close of the fiscal year the following disasters have occurred:

On Sept. 13, 1915, the Fabre Line steamship "Sant' Anna," bound from New York to Naples with 1,700 Italian reservists and crew aboard, caught fire in mid-ocean and all persons on board were saved. The S O S call brought the steamship "Ancona" to the assistance of the disabled vessel and 600 persons were taken off. The "Sant' Anna" then proceeded to port, convoyed by the "Ancona," and the entire 1,700 passengers and crew saved.

Six days after the "Sant' Anna" disaster, the Greek liner "Athinai," bound from New York to Piraeus, caught fire in mid-ocean and was abandoned by the passengers and crew, numbering 470. The call for assistance was answered by the steamships "Tuscania" and "Roumanian Prince"; 341 persons were taken on board the "Tuscania," the remaining 129 being taken off by the "Roumanian Prince." The vessel was entirely destroyed.

The use of radio apparatus on vessels carrying passengers, or with 50 or more crew, is now accepted as essential to the safety of those on board, and the report of the "Athinai" shows conclusively that many persons might have been lost and perhaps the cause of the disaster never known had not this vessel been equipped with radio apparatus.

How to Build a Photophone

Those who are experimenting with selenium will find this manometric flame very useful in their research work. It can be employed in transmitting wireless telephone messages by the use of a light beam acting upon a selenium cell. It can also be successfully employed in recording voice sounds by the addition of a revolving mirror.

Fig. 1. The Completed Photophone.

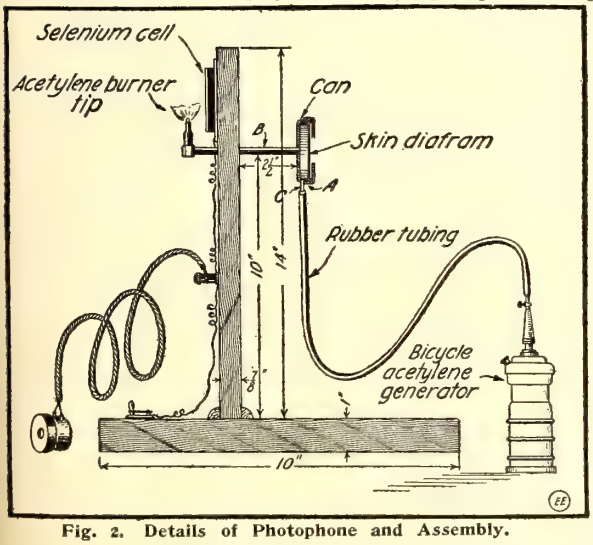
The complete apparatus as shown in Fig. 1 was built by William J. Hammer, of New York. A selenium cell is placed behind the flame-tip as perceived and is connected in series with two batteries and 'phones, as photograph shows. In Fig. 2 the constructional details are given. The very first thing to build is the stand, which consists of two strips of well-seasoned wood of either oak or mahogany. It should be made of ¾-inch stock, and the details of same are given in both figures.

The most important apparatus of this outfit is the instrument A, which causes variations in the flame at the tip, and this is made from an old shoe blacking can. The can is first thoroughly cleaned by applying hot water and a rag; after this is done a 1-inch hole is made in the cover, as seen in Fig. 2. This can be made by either drilling or else sawing it out with a jeweler's saw. A $\frac{5}{16}$-inch hole is drilled in the center of the back for securing a brass tube B. This tube should be well soldered on the back and is used for transmitting the gas to the tip. Another tube C of the same size is secured on the bottom of the case, and this also should be soldered, and is connected to an acetylene gas generator by means of a rubber tube. The diaphragm is next provided, which consists of goldbeater's or pig's bladder skin of very light quality. First the latter is laid across the case with its cover removed and the skin is then tightly stretched across the edge of the box, and finally the cover is placed over the diaphragm. This is firmly pressed into its proper place. The edge of the cover is next soldered all around the case in order to make it perfectly gas-tight.

Having finished all this, a hole is made in the upright wooden standard 10 inches from the bottom and 2 inches from the side. The tube B is now carefully inserted through this hole and firmly held in place by applying some sealing wax around the tube. An ordinary acetylene gas tip is procured and placed over the end of the tube as observed.

A small selenium cell is now placed in back of the flame tip. This is held in position by means of two brass strips, which are screwed on to the base by wood screws. Two binding posts are next placed on the upright support and these are connected to the cell, which in turn is connected in series with a telephone receiver and several batteries, as the photograph depicts.

The experimenter who is not familiar with the working principle of this instrument will find the following simple explanation quite satisfactory: At first, when the gas enters the chamber, a straight flame is produced at the tip; but as soon as one begins to talk near the diaphragm at A the volume of gas is interrupted, and consequently the flame is varied in brilliancy, this being directly proportional to the intensity of the sound against the diaphragm. Therefore the change in the voice will be reproduced in the flame, and in consequence will affect the sensitive selenium cell, which then operates the telephone receiver according to the variation of resistance. As this is governed by the gas flame, therefore the voice is accurately duplicated at the receiver by merely talking against the skin diaphragm. Of course, it should be understood that the selenium cell can be placed at any distance from the flame, light will be required. This principle, greatly enlarged upon, as by using an electric arc lamp, has enabled speech to be transmitted for several miles; one record attained by the late Herr Ruhmer having been 14 miles.



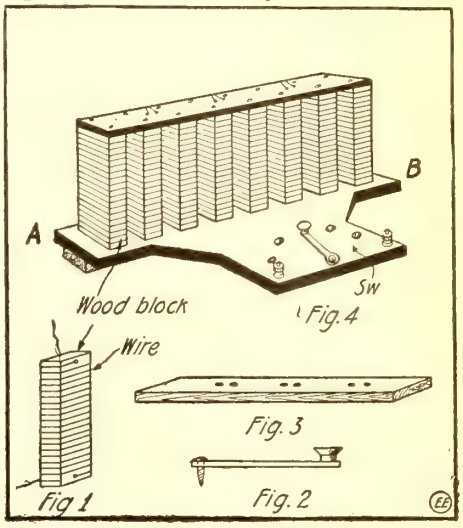


Fig. 2. Details of Photophone and Assembly.

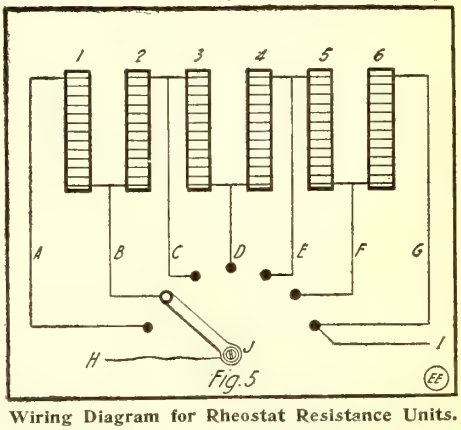
RHEOSTAT FOR SMALL MOTORS.

This rheostat is composed of a base-board, eight hardwood blocks and a strip of wood for the top piece, used as a binder. The blocks are ¾ inch thick, 1½ inches wide and 4 inches long. A hole is made through both ends of the block, through which one end of wire is passed. The wire is then wound around the block, taking care to wind it evenly and leave about ⅛ inch between each strand. Put the wire through the opposite hole and clip it off, leaving just enough wire so that connections may easily be made. This step is shown in Fig. 1.

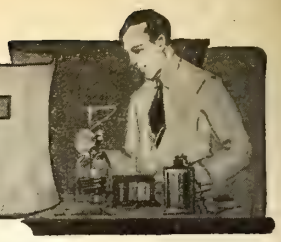


Parts and Assembly of Rheostat for Controlling Small Motors.

When the eight blocks are wound mount them at the rear on the base-board; cut in the design shown in the drawing, the rear measuring 9 inches from A to B in Fig. 4. Screw the strip to each one of these blocks as shown in figure. The switch may be made of suitable metal 3 inches long, ½ inch wide. At one end glue half of a spool as shown in Fig. 2. When completed it should look like Fig. 4.

The connections are made as follows: Coil Nos. 1 and 2 are connected at the bottom, Nos. 2 and 3 are connected at the top, and so on to the end. The leading-in current is connected at pole H, and so on to J, while the leading-out wire is made fast to pole I.

The switch arm is moved over to the first contact point, which starts the current through wire A down through coil 1, up coil 2, down coil 3, up 4, and thus through 6 and out wire G. Should this offer too much resistance, move the switch to contact 2, which sends the current through wire B, up through coil 2, down 3, up 4, etc., and thus out wire G.



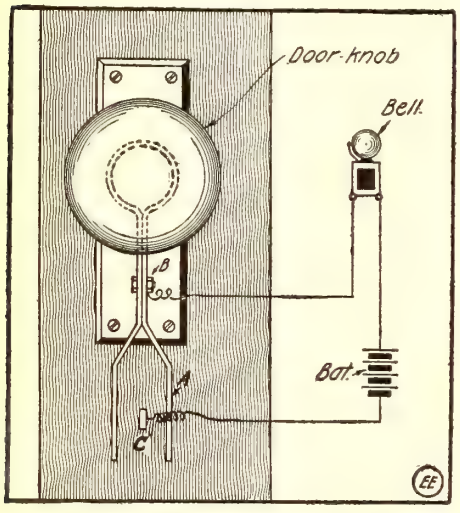
Wiring Diagram for Rheostat Resistance Units.

The contact points and binding posts may be made or bought at very low cost.

Contributed by JACK CRANDALL.

HOW TO MAKE IT

This department will award the following monthly prizes: FIRST PRIZE, $3.00; SECOND PRIZE, $2.00; THIRD PRIZE, $1.00.
The idea of this department is to accomplish new things with old apparatus or old material, and for the most useful, practical and original idea submitted to the Editors of this department, a monthly series of prizes will be awarded. For the best ideas submitted a prize of $3.00 will be given; for the second best idea a $2.00 prize, and for the third best a prize of $1.00. The article need not be very elaborate, and rough sketches are sufficient. We will make the mechanical drawings.



FIRST PRIZE $3.00.

A SIMPLE DOOR BELL ALARM.

An easily made switch for ringing a bell to let me know when anyone opens the door of my shop is here described.

A metal strip (A), preferably of copper, should be bent into a small circle at the middle to fit over the doorknob bar. A small bolt will draw it up tight around this bar at (B). Place between the prongs and fasten to the door a metal strip (C) and the device is complete.

By connecting a battery and bell as shown a slight turn of the knob either way will throw one prong or the other against (C), completing the circuit and ringing the bell.

Electric Call Bell Attachment for Door Knobs.

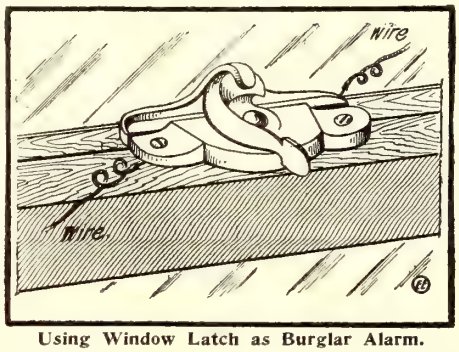
Contributed by C. REX GILBERT.

METHOD OF THREADING HOLES IN CARBON AND OTHER MATERIALS.

The following is a suggestion for threading holes in pieces of carbon and other material without taps. Bore a hole in the carbon a little deeper and with a larger diameter than the length and diameter of the screw you intend using. Then nick the edge of the hole with a file or saw. Melt sufficient lead to pour into the hole, and while the lead is still in a molten state insert the screw. When the lead has hardened the screw may be removed with a screw-driver.

Contributed by PHIL TAUB.

THE INITIAL STEP.



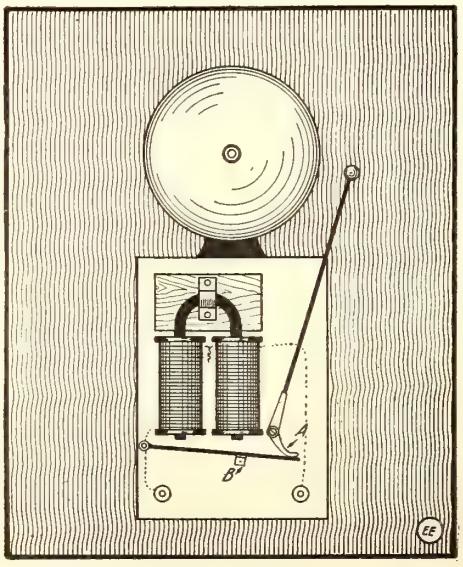
"I hear, old man, that you are going in for wireless. What have you got toward it?"

"A catalog, two binding posts and a buzzer."

SECOND PRIZE $2.00.

USING WINDOW-LATCH AS A SWITCH.

A window-latch can be used as a single-pole, single-throw switch by connecting your wires as shown in the diagram or by



Using Window Latch as Burglar Alarm.

connecting the wires as on an ordinary single-pole, single-throw switch. The latch may be of any metal. This is useful for closed-circuit burglar alarm circuits.

Contributed by BERNARD COHEN.

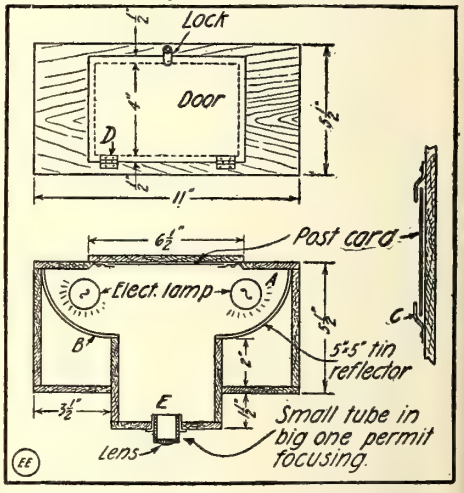
A SOMEWHAT DIFFERENT ELECTRIC BELL.

The bell herewith illustrated is very simple, but a few words may make its construction clearer. It differs from the ordinary style of bell in that it has a hinged armature instead of a spring one. The clapper holder A is made from a piece of heavy copper. A hole is drilled and tapped

An Electric Bell of Radical Design.

to take an 8-32 brass machine screw. A further hole is then made in the base into which the screw will fit very tightly. Before putting the clapper holder on a brass nut should be put on the screw for convenience in making the connection. In operation the bell works as follows: When a current flows through the magnets the armature is drawn up against the pole pieces which actuate the clapper. When the clapper strikes the bell the arm of A should just barely be clear of the armature, thus breaking the circuit. The armature drops back before the clapper and when the latter drops the circuit is again completed.

Contributed by SELMER WICK.



THIRD PRIZE $1.00.

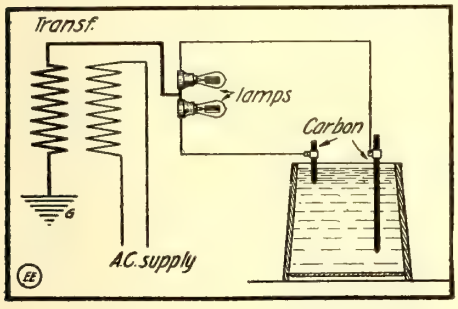
POST CARD PROJECTOR.

The materials required for this device are two electric lamps and two sockets. Also two pieces of tin 5x5 inches, "B"; two strips of tin 1x4 inches, "C," bent as shown; two small hinges, "D"; a lens having about 5 inches focal length, "E," and some pieces of hard wood.

From the hard wood construct a box 11 x5½x5½ inches, as shown in illustrations. Then put the lamps, reflectors, lens, door with post card holder and hinges on same and connect lamps with batteries. To operate put the postal or other picture in holder, close the door and take the machine into a dark room. Then hang a curtain 7x5 feet on the wall and focus the lens.

Contributed by ARTHUR PAUL.

Home-Made Post Card Projector.



DRY CELLS SHOULD BE DATED.

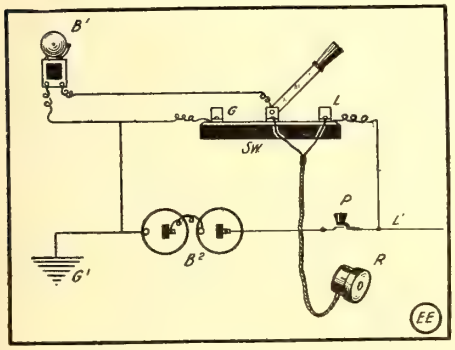
Dry batteries are useful for many experimental purposes, but have the disadvantage of giving no external indication of being run down. It is a good plan, therefore, to label each cell with the date on which it was put into use. This is especially useful in connection with electric bells, for if a defect occurs one must suspect either the bell, the battery or the wiring. If the battery is seen to have been in service for a long while, it will be advisable to try a new cell rather than spend much time testing the wires or adjusting the bell.

Contributed by H. J. GRAY.

AN ELECTRICAL WATER LEVEL INDICATOR.

A novel form of electrical water level gauge is described by a writer in *Power*. This arrangement is particularly adapted to gauge the depth of water in shallow pans or reservoirs, where, for instance, the total depth is only 5 inches from the overflow outlet to the bottom of the pan. A float of the usual type was tried, but found to be impracticable. As the illustration shows, a 200-watt, 2-coil A. C. transformer was connected with a pair of lamps, which were in turn connected in multiple to the water level in the pan. The terminals in

Unique Water Level Indicating Scheme.



the tank were a pair of arc lamp carbons, one having been adjusted to make contact with the water just before the pan became dry. One side of the transformer was grounded as perceived. One of the lamps was red, while the other was left plain; a red light indicating *overflow*, while a white light denoted *safe water level*. No light indicated *no water* in the tank.

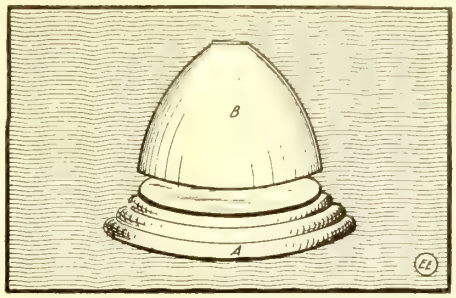
A SHORT DISTANCE TELEPHONE.

Chums can communicate with each other very easily, using the following system, provided the distance between their houses is not much over 200 feet or so.

Connect the following apparatus according to the diagram: B^1, electric bell; Sw. S. P. D. T. switch; R, 75-ohm telephone receiver; B^2, batteries; P, push button; G^1, ground (connected to water pipe); L^1, line or wire running from one house to the other.

Operation: When the phones are not in

A Simple Short Distance Telephone Set.



use place the blade of switch on L. Now if you wish to talk to your friend push the button P several times and then throw the blade to G. Your friend, hearing the bell, also throws his blade to G and says, "Hello!" through the receiver R, and you hear the reply in your receiver. (This being used both for transmitter and receiver.)

When the conversation is over the blades of Sw. must be thrown back to L, making the line ready for calling again.

Contributed by JAMES R. HOPKINS.

HOW TO MAKE A PARABOLIC REFLECTOR.

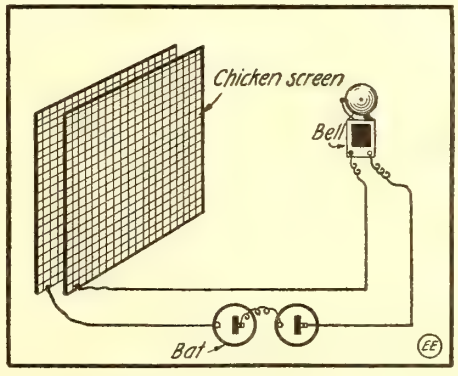
When making up electric bicycle headlights, etc., amateur mechanics are in need

Parabolic Reflector Made from Brass Fixture Canopy.

of a parabolic reflector, which can be made very easily as follows:

Procure from any dealer in electrical supplies a brass fixture canopy of the size required and cut off part "A" as shown in illustration. Part "B" will then serve as the reflector. Then polish the interior and proceed to silver-plate same. A silver-plating fluid can be made by dissolving 1 ounce nitrate of silver in 12 fluid ounces of soft water and adding 2 ounces cyanide of potash. Mix this with enough fine whiting to make it the consistency of thick cream, and with a piece of clean rag or cotton apply same to the polished interior of your reflector. Let it dry and brush off the whiting and you will have a good, silver-plated parabolic reflector.

Contributed by GEO. NIEDERHOFF.

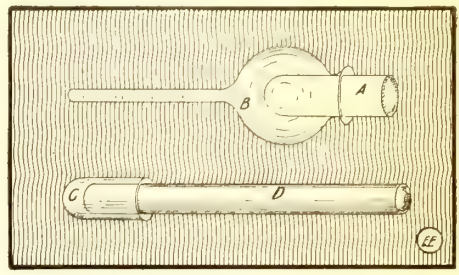


A SAFETY CHICKEN-COOP.

If one has a chicken-coop and is troubled with chicken thieves, he may avoid this by constructing a safety coop.

Take an abundance of wire screen and surround the coop with it. Fasten it to the ground so that it is firm. Then take another screen of the same length and fasten it to the ground so that it is about 1 inch away from the first screen. Take batteries and a bell and connect them with the screens as the diagram shows. Whenever a thief comes to eliminate some of your fowls, he brushes up against the outside screen or leans against it, and thereby closes the circuit, ringing the bell which may be located at any desired place.

Contributed by J. MARCHETTI.

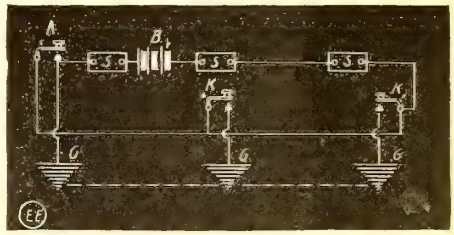


(The author of the above doesn't state what happens when a strong wind blows or when a "non-burglar" accidentally leans against the fences! Ed.)

Pressure Against Outer Screen Rings Bell of this Chicken Thief Alarm.

EXCITER FOR CHARGING ELECTROSCOPES.

It is often necessary to test the polarity of an electrostatic charge by means of an electroscope that has been charged with electricity of known sign, either positive or negative. When the charged body which is to be tested is brought near to the instrument the leaves diverge more widely if the sign is the same, or collapse if it is opposite. The usual method of giving the initial charge to the electroscope by induction is inconvenient, because the induced charge is of opposite sign to that of the charging body. By use of the device shown in the illustration either a positive or negative charge may be given direct, and, while strong enough for the purpose, there is no risk of tearing the gold leaves by over-charging.



Miniature Static Generator for Exciting Electroscopes.

A thin brass tube A closed at one end is attached to a glass handle B with a little elastic glue or other non-conducting adhesive. A broken "thistle" funnel with the stem cut short and closed in a blowpipe flame makes a capital handle. The open end of the tube must be rounded, or what amounts to the same thing from an electrical point of view, turned in so that the sharp edge is inside. This must be lined with fur, the skin side of the fur being secured to the metal with glue. A smaller metal tube C, similarly rounded at the open end, is secured on the end of a glass rod D, which serves as an insulating handle. Mark the large tube "positive" and the small one "negative." The small tube should be kept inside the larger one when not in use. If quickly withdrawn both become oppositely charged, and either may be used for charging the electroscope or for any other purpose requiring a very weak charge of known sign.

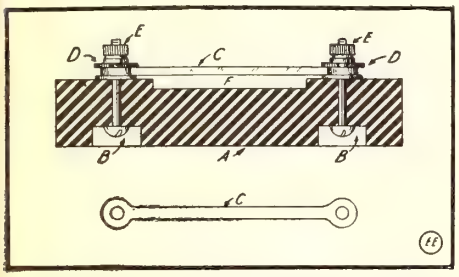
UNIQUE TELEGRAPH SYSTEM.

I thought that it might be of interest to some readers to know that around Spo-

Telegraph System Utilizing Three Sounders and Common Battery.

kane, Wash., some of the farmers use the wire fences for private telephone lines.

The following connections were used by three of us boys on a telegraph line. In the diagram herewith, S.S.S. are sounders, K.K.K. the keys, F.F.F. the ground connections, and B is a battery of either wet or dry cells. The chief advantage of this is that there are no switches, also it is an open circuit system.



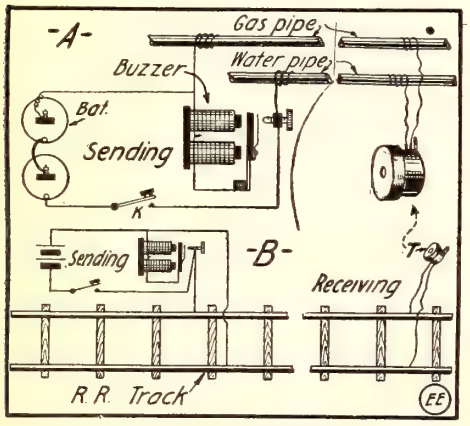
Contributed by JOHN B. MOORE.

. Shaking the transmitter will oftentimes improve the enunciation on the telephone.

FUSE FOR BATTERY CIRCUIT.

While a fuse block is not essential for a battery circuit, there is a certain satisfaction in following out the general plan of large power stations, where a properly proportioned fuse is quite indispensable. The illustration shows a simple fuse block that can be made by any experimenter, the fuse itself being quickly renewed when necessary.

The several parts are mounted on a block of wood A that has been well impregnated by soaking it in melted paraffine wax. Two



Tinfoil Fuse and Block for Battery Circuits.

bolts B, B, are passed through the underside, the holes being countersunk to accommodate the heads. The bolts may be an inch apart, and serve to hold a strip of tinfoil C, two brass washers shown at D being used to avoid tearing the foil when tightening up the nuts E, E. The strip of foil should be of uniform width, except at the ends, one-eighth inch or less being sufficient for the middle portion. If a small strip of glass F can be cut from an old negative or microscope slide and let into the wood between the bolts it will be an advantage.

Contributed by H. J. GRAY.

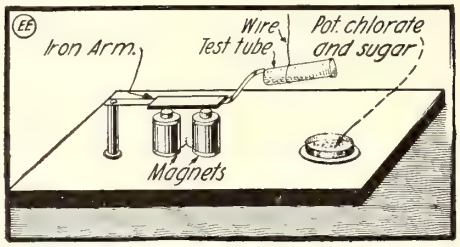
BUZZER TELEGRAPHS TWO MILES.

In the October issue of your magazine I noticed in an article where an English experimenter had sent messages over water pipes for one-quarter of a mile. He used a

Telegraphing by Buzzer.

sensitive galvanometer to receive signals with.

My method is cheaper and more efficient. I use a common buzzer and an ordinary 75-ohm telephone receiver. Both gas and water pipes are used, and the danger of a short-circuit by using only water pipes is averted.



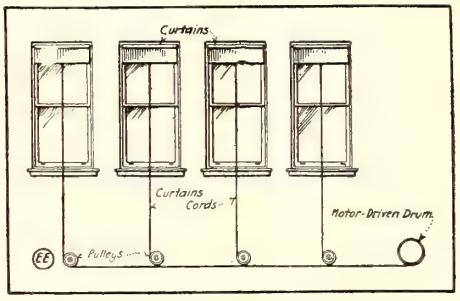
Connect the instruments as at A. The signals come in exactly like wireless buzzes. The farthest distance we ever tried was 1¼ miles, and the signals came in loud and clear.

We also tried this method along the railroad tracks B, and it worked over a distance of two miles.

Contributed by B. SCHUMM.

AN ELECTRIC IGNITER.

This apparatus is intended for the experimenter who does not possess a spark coil with which to ignite fireworks or chemicals at a distance. First wind two small magnets with No. 20 D. C. C. wire



Useful Electric Igniter Subject to Remote Control.

and make an iron armature with a spring brass arm and a clip on the end of the armature. This clip holds the test tube from overturning. When clip is released, gravity upsets the tube which contains a few drops of sulphuric acid. This falls on a mixture of potassium chlorate and sugar. Take equal amounts of sugar and potassium chlorate. This mixture ignites and sets fire to a fuse.

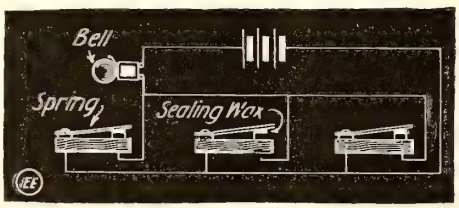
MOTOR RAISES AND LOWERS WINDOW CURTAINS.

A unique device for raising or lowering

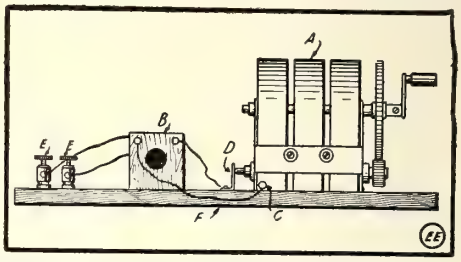


Raising Window Shades by Motor.

a number of window curtains has been adopted by a large Western school, says a writer in the *Electrical World*. As perceived, each curtain has a cord secured to same, and these all pass over a series of pulleys down near the floor, and the cords, in turn, pass to the motor-driven drum, as indicated in the illustration. In this way a few turns of the motor will lower or raise the curtains, according to the direction in which the motor is driven. These refinements are not, of course, practical in the ordinary house or hall, but in school or other buildings where there are a large number of windows which are to have their shades repeatedly changed during the day this scheme should find considerable favor.

AN AUTOMATIC "FIRE" ALARM.

This device is very practical for giving an alarm of "fire" in any room or shop. It works on the same principle as the fuse;



Electric Fire Alarm Using Sealing Wax Fuses.

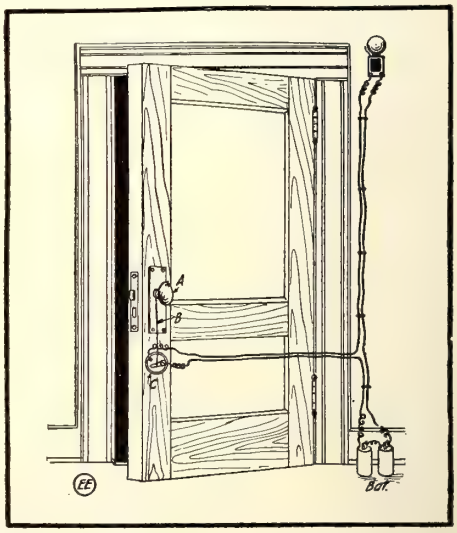
a bit of sealing wax being used to break the circuit. With very little heat, the wax is melted, the steel spring then snaps down on the conductor terminal, thus completing the circuit and the alarm is sounded.

Contributed by WILLIAM WILLIAMS.

A HANDY A. C. GENERATING SET.

I give herewith brief description of a useful A. C. electric generator which can be made from the parts of an old telephone. Referring to the diagram A is a telephone magneto, B a telephone induction coil to step down the high voltage of the magneto to that of small motors, battery lamps, etc. One of the secondary

Small A.C. Generating Plant with Transformer.



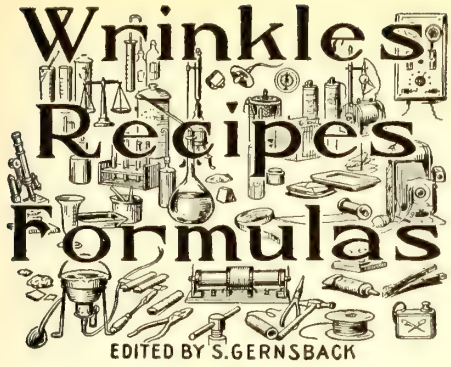
wires of the coil is connected to the contact D, the other to the magneto frame. The primary wires are connected to the binding posts EE. The base is of wood and should be of a suitable size. If the generator is run by a motor small induction coils can be operated nicely.

Contributed by AN EXPERIMENTER.

A SIMPLE BURGLAR ALARM.

This simple burglar alarm can be attached to any door with very little trouble. A string, B, is fastened to the knob, A, by winding it around the knob a few times then tying. The string is then attached to a switch, C, which makes a circuit with the contact when the knob is turned.

Contributed by CARL HANCOCK.



Burglar Alarm Employing String to Connect Doorknob and Switch.

REPAIRING SMALL TUNGSTEN LAMPS.

Don't throw away your burned-out flashlight bulbs. If the bulb itself is not cracked or broken connect it across the secondary of a ¼ or ½ inch spark coil and close the primary circuit for an instant, *not longer*. When you test your lamp on a battery circuit you will find that the two ends of the filament have been welded together and the light is as good as new.

(This does not always work, but it is worth trying.—*Editor.*)

Contributed by C. M. CROUCH.

Under this heading we will publish every month useful information in Mechanics, Electricity and Chemistry. We shall be pleased, of course, to have our readers send us any recipes, formulas, wrinkles, new ideas, etc., useful to the experimenter, which will be duly paid for, upon publication, if acceptable.

FORMULA NO. 19.

Blackings and Polishes for Leather Harnesses, Etc.

1. *Harness Blacking.*—Melt together 2 oz. of *Mutton Suet,* 6 oz. of *Beeswax.* Add 6 oz. of *Sugar Candy,* 2 oz. of *Soft Soap,* 2½ oz. of *Lampblack,* ½ oz. of *Powdered Indigo.* Mix thoroughly and add ¼ pint of oil of turpentine.

2. *Harness Blacking.*—Melt together 4 oz. of *Gelatin,* 3 oz. of *Gum Arabic,* ¾ pint of *Water.* Add when dissolved 7 oz. of *Molasses,* 5 oz. of *Fine Powdered Animal Charcoal.* Heat gently, stirring all the time until the compound is of proper consistency when cold. Must be kept corked.

3. *Polish for Carriage Harness.*—Dissolve 3 sticks of black sealing wax in ½ pint of *Alcohol* and apply with a sponge.

4. *French Blacking to Restore Soiled Harness.*—Take 4½ lb. of *Stearine* in thin sheets. Mix with 6¾ lb. of *Turpentine.* Heat in a water bath, during continual stirring; then add 3 oz. of *Animal Charcoal,* place the whole in another vessel and stir so as to prevent its crystallization. It must be warmed when using and rubbed on with a cloth as quickly as possible, giving it a very thin coat, and when nearly dry polish with a silk cloth.

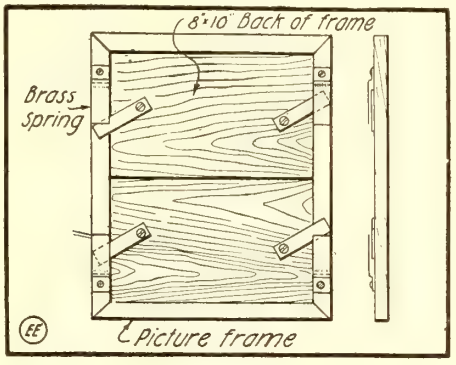
5. *Waterproof Harness Paste.*—Put into a glazed vessel and melt over a fire 28 oz. of *black resin,* when dissolved add 3 oz. of *Beeswax.* When this is melted remove from the fire and add ½ oz. of fine *Lampblack,* ½ drm. of *Prussian Blue in Powder.* Stir well together and add *Turpentine,* enough to form a thin paste. Allow to cool. Apply with a sponge and polish with a soft brush.

6. *English Ball Blacking for Harness.*—1 oz. of *Lard,* 1 oz. of *Beeswax,* 8 oz. of *Ivory Black,* 8 oz. of *Sugar,* 4 oz. of *Linseed Oil,* 2 oz. of *Water.* Melt the wax and stir in the other ingredients, and when cold roll into balls and use.

7. *Vaseline Harness Composition.*—¾ oz. of *Prussian Blue in Powder,* 4 oz. of *Lampblack,* 2 oz. of *Molasses,* 2 oz. of *Soft Castile Soap.* Warm and mix together in a mortar. Then add 6 oz. of *Vaseline,* 5 oz. of *Ceres,* ½ oz. of *Yellow Resin.* Melt together and add sufficient turpentine to give proper consistency. Mix thoroughly.

8. *Oil for Farm and Team Harness.*—Melt 3 lb. *pure Tallow,* but do not heat it up to a boil; then pour in gradually 1 lb. neatsfoot oil, and stir until the mass is cold. If properly stirred, the two articles will become thoroughly mixed and the grease will be smooth and soft; if not well stirred, the tallow will granulate. Add a little bone black for coloring.

9. *Lacquer for Harness.*—5 parts of *Colophony,* 1 part of *Lampblack,* 2 parts of *Mastic,* 5 parts of *Sandarac,* 20 parts of *Shellac,* 5 parts of *Turpentine,* 100 parts of best *Spirits.*



10. *For Russet Leather Harness.*—Mix together 1 part of *Palm Oil,* 3 parts of *Common Soap,* and heat up to 100° F., then add 4 parts of *Oleic Acid* and 1¾ parts of *Tanning Solution* (containing at least 1-16 of *Tannic Acid.*) Stir until cold.

S. G.

EMERGENCY BLUE-PRINTING.

Recently I had occasion to make a blue-print drawing in a hurry, but found I did not have either a frame or the blue-print paper large enough for the work at hand, so the following kinks may come in handy for some readers of your magazine. To make the frame I took down a picture from the wall and removed everything except the glass and frame. I then screwed four pieces of spring copper on it as shown in the drawing. The size of the picture frame was 16x20 and, having two backs for the regular 8x10 photographic frames, I fixed them up as shown. This frame proved to be very serviceable and filled the requirements which were needed.

To make the blue-print paper proceed as follows: Obtain a fairly good grade of drawing paper (Rives or Saxe paper, if it

Making an Emergency Blue-Printing Frame of Large Size.

can be obtained), and cut down to the required size. Next make up a blue-print solution as follows:

Solution A.—Water, 2 ounces; potassium ferricyanide (red prussiate), 120 grains.

Solution B.—Water, 2 ounces; ammonia citrate of iron, 140 grains. (Any proportion of the above can be made.)

When they are thoroughly dissolved, mix and filter, and always keep in a clean bottle. Be careful not to let too much strong light act upon this solution.

The best way to sensitize the paper is to work by an orange light similar to the light used in bromide printing in photography. Float the paper on this solution until it lies perfectly flat. Do not take it out of the solution carelessly, but slide it out by grasping two corners, sliding it over the surface of the water. If it is desired to keep some of the paper for future use this can be done by rolling it up, with the sensitized surface on the inside, and keeping in a tin box free from light.

If any part of the above instructions are not clear I shall be very glad to try and explain anything in doubt upon receipt of a self-addressed envelope.

Contributed by A. WILSDON.

To Remove Oil Stains from Leather.—Cover the spot with *Spirits of Sal-ammoniac;* allow it to act for a short time, cleaning with clear water; repeat until the spot is removed, taking care not to affect the color of the leather.

A GOOD SILVER WASH.

Take 1 ounce of pure nitric acid, 1 silver dime (or, better, a Canadian five-cent piece, which is also silver) and 1 ounce of quicksilver. These ingredients are now placed in a glass vessel and left until they are completely dissolved. Then add a pint of water and next enough powdered whiting to make the whole into a powder. This silver wash may be used on brass, copper, German silver, etc.

CEMENT FOR ATTACHING GLASS TO METAL.

Take about 2 ounces of a thick solution of glue and mix with it 1 ounce of linseed oil varnish and ½ ounce of pure turpentine. This mixture is next boiled in a covered crock and is then ready for use. The articles after being cemented should be clamped together for several days to allow the cement to set properly.

A GOOD SOLDERING SOLUTION.

Procure about 5 cents' worth of muriatic acid and add as much pure zinc as it will dissolve. If a little rain-water is added it will somewhat improve the mixture. The articles to be soldered should be thoroughly cleaned of every trace of dirt. The soldering solution is next applied with a wire brush to the cleaned surface. With this solution the solder will stick every time.

Contributed by WM. A. CAWLEY.

SILVER PLATED PENNIES.

In a solution of mercuric nitrate place a cent so that the coin will be completely covered by the liquid. A chemical reaction immediately takes place; the copper, having a greater affinity for the nitrate than the mercury, forms a copper nitrate, causing the mercury to be deposited on the cent, which gives it a silver-plated appearance.

If mercuric nitrate cannot be bought it can easily be made by dissolving a small globule of mercury in a little concentrated nitric acid, warming, if necessary, to start the reaction.

Contributed by PAUL JENKINS.

HOW TO CUT BRASS AS WELL AS GLASS IS CUT WITH A DIAMOND.

With a quill pen dipped in a strong solution of alcoholic corrosive sublimate (*careful; strong poison*) draw a line on the brass. After letting this dry, go over the line with the pen dipped in nitric acid. Then the metal may be broken as glass is cut with a diamond.

Contributed by JOHN SCHMELZEIS.

MISCELLANEOUS FORMULAS.

A good metal polish may be made as follows: Take wood alcohol, 3 parts; aqua ammonia, 1 part; prepared chalk, ½ part. Apply the polish with a flannel and when dry wipe off. Shake the polish before using to get the chalk stirred up.

Carpet soap can be made as follows: Three small bars of good white soap, 2 gallons of water, 1 10-cent bottle of household ammonia, ½ box of borax and 10 cents' worth of tartar. Dissolve the soap in water on top of stove; then add other ingredients. Let boil 10 minutes and then remove from the stove.

A silver plating for steel can be made as follows: Lunar caustic, 11 parts; sodium hyposulphite, 20 parts; sal ammoniac, 12 parts; whiting, 20 parts, and distilled water, 200 parts, mixed together. Before applying the silver plating to the article clean off all grease.

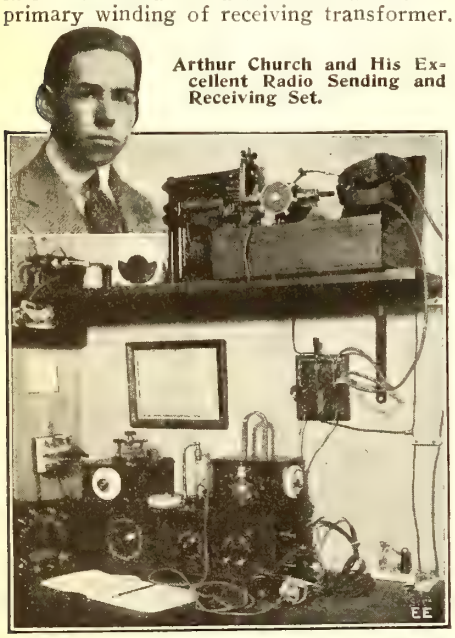
WITH THE AMATEURS

Our Amateur Radio Station Contest is open to all readers, whether subscribers or not. The photos are judged for best arrangement and efficiency of the apparatus. To increase the interest of this department we make it a rule not to publish photos of stations unaccompanied by that of the owner. Dark photos preferred to light toned ones. We pay each month $3.00 prize for the best photo. Make your description brief. Address the Editor.

AMATEUR RADIO STATION CONTEST.



Monthly Prize, $3.00.

This month's prize winner.

ARTHUR CHURCH'S PROGRESSIVE WIRELESS STATION.

I present herewith photograph of my wireless station. The transmitter consists of a 1-K. W. Thordarson transformer and line protector, moulded condenser, rotary spark gap and hinged type oscillation transformer.

The receiving set consists of a special loose coupled tuner of my own design and construction, three variable condensers and fixed condenser, audion detectors and E. I. Co. "Government" type 3,000-ohm receivers. A pair of Brandes superior 'phones are also seen in the photo. A special switch on the left end of the cabinet throws the E. I. Co. .01 M. F. variable condenser either in series with antenna circuit or across the primary winding of receiving transformer.

Arthur Church and His Excellent Radio Sending and Receiving Set.

A Mignon vario-selective coupler is sometimes used with very good results, but is intended especially as a portable receiver in which capacity it is admirable indeed. I am using a multi-audifone equipment, and the received signal strength at this station is simply wonderful. N.A.R. comes in at noon loud enough to be read with 'phones off—a distance of over 1,500 miles. W.H.K. and several other stations are audible at times 40 feet from 'phones. Regular communication is carried on with various stations within 300 miles.

Two aerials are employed; one for 200 meter work and the other for longer wave length. The latter is 300 feet long, stretched from a 100-foot mast to a 60-foot pole at the station. I hold a second grade commercial radio operator's license and my official call is 9.W.U.

ARTHUR B. CHURCH.

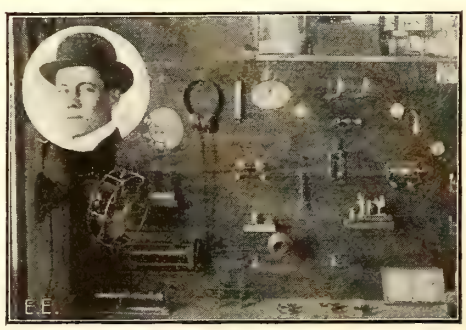
Lamoni, Iowa.

LAKE PARK RADIO CLUB.

The accompanying illustration portrays some of the apparatus in use at the main station of the Lake Park Radio Club at Des Moines, Iowa.

Radio Station of the Lake Park Radio Club.

The aerial is of the "L" type and contains four wires. We can receive the following stations easily: Ames, Iowa State Teachers' College, East and West High Schools, and we also hear many near-by amateurs.



The following gentlemen hold office: Roy Smith, president; French Holebrook, vice-president; James R. Allen, treasurer; Kerby Moran, secretary.

LAKE PARK RADIO CLUB,
Per James R. Allen, Sec'y.

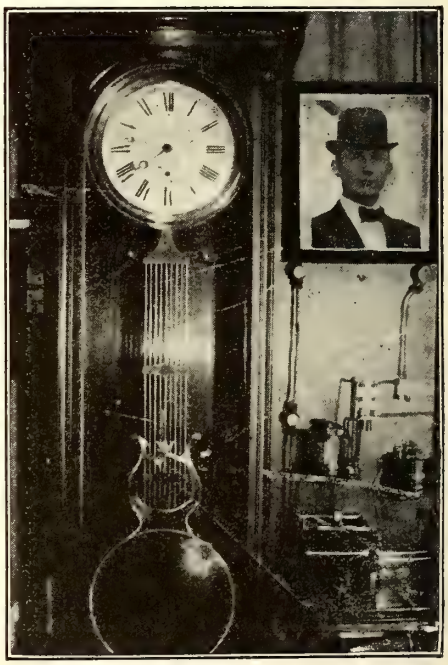
Des Moines, Iowa.

RADIO STATION OF CHARLIE BARE.

Herewith are presented illustrations of my wireless set and myself. I am using a one-half kilowatt, closed core transformer at present, with a quenched spark gap of my own make. The detectors are also of my own construction. My switchboard is placed 40 inches from the wall, thereby allowing space behind it for tools and materials necessary for making repairs. The aerial consists of four stranded wires, each 75 feet long and 70 feet high.

Well Arranged Station of Charlie Bare.

I am also carrying a line of wireless supplies in my office and use my station extensively for demonstrating.



CHARLIE BARE.

Mt. Carmel, Ill.

RADIO TIME SET OF J. B. MACKEY.

About seven months ago, after having read several interesting articles in *The Electrical Experimenter* on wireless and wireless time receiving stations and being a jeweler, I became very much interested in a wireless time receiving station.

Our city gave me permission to attach one end of my aerial to the water tower, which is 110 feet high. This tower being 275 feet from my store gives me an aerial 253 feet between spreaders (I used four wires in aerial). My store is a two-story building, so I only had to erect a 70-foot mast to make it 110 feet at that end. Now comes the interesting feature to the jeweler. On top of this mast that stands 110 feet high over my store I installed a 500-watt Ruby electric light. I made a little attachment that you may notice in the

Wireless Time Station of J. B. Mackey.

picture, which I attached to the pendulum of my regulator, making a contact every time the pendulum swings back and forth, flashing the time out to the public in perfect synchronism with the time signals given out by Arlington (N. A. A.). The last minute preceding the hour of time the light is made to burn continuous by means of a two-way switch, going out absolutely on the hour. This feature of wireless time has proven a big advertisement for me, and I believe it will for any jeweler. People in a neighboring town about five miles away are able to get correct time regular as it is flashed out. This method of transmitting time has been reported as far as 15 miles from my store. Many people on the streets, when the time is being given, stop and compare their watches to the second.

J. B. MACKEY.

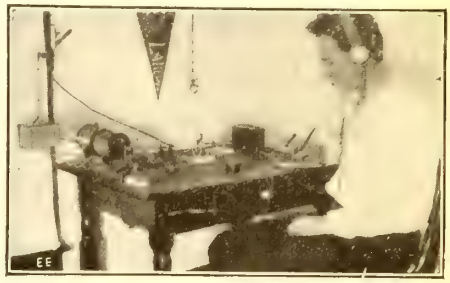
Uniontown, Ala.

WIRELESS STATION OF ROY WUENN.

I am submitting herewith a description and photograph of my set for the Amateur Wireless Station contest. The transmitting set consists of 1½-inch and 2-inch coils, helix, rotary and stationary gaps, two condensers (one a Leyden jar condenser and the other a glass plate type, connected together) and a key. The receiving set has a De Forest rotary variable condenser, Blitzen variable condenser, sliding plate condenser, variometer, tuning coil (800 meters), transformer (3,000 meters), transformer (5,000 meters), two fixed condensers and three detectors, galena, commercial silicon and Radioson detector. The aerial consists of six strands on 12-foot spreaders. It is of the inverted "L" type, 150 feet long, suspended between a 60-foot pole and one on top of the house.

Complete Radio Set of Roy Wuenn.

I purchased some of my instruments from the large wireless station that was at Michigan City. I have received many long-distance station signals, having caught baseball scores sent from New York to Chicago. I shall be glad to communicate with anyone within my range. ROY WUENN.



Michigan City, Ind.

THE IONIZED UPPER AIR.

The theory that the upper layers of the atmosphere are ionized and therefore conduct electricity, first suggested by the late Professor FitzGerald in 1893, has been extensively utilized in recent years to explain the law of decrease of the intensity of radio-telegraphic signals with distance. In an article in the *Revue générale des Sciences* Professor H. Nagaoka, of the University of Tokio, attributes this ionization to two causes. The first is the ultra-violet light of the sun, which he believes is capable of ionizing the atmosphere down to about 40 kilometers from the earth's surface. The second is the stream of electrons emitted by the sun, which, owing to the magnetic fields of the sun and the earth, describe paths far from straight and account for the ionization of the upper atmosphere at night. The greater height of the reflecting layer at night and the consequent reduction in the number of reflections of the waves at the ionized layer and at the earth's surface account for the better transmission of signals at night. The under concave surface of the ionized layer above a station at which the sun is rising focuses the waves from the west near the surface of the earth, and so gives the good signals at dawn. A similar focusing of the waves from the east occurs at sunset. The effect of solar eclipses is explained in the same way, and Professor Nagaoka points out that as the period of an electrical oscillation on the sun is 6.5 seconds, there should be a corresponding period in the stray signals at terrestrial stations. He hopes radio-telegraphic observers will succeed in detecting this period exactly. This opens an interesting field of experiments for the amateur interested in such work.

MAX CLINCH A RADIO ENTHUSIAST.

As I am a regular subscriber to *The Electrical Experimenter* I take this opportunity of tendering photo of my station and myself for entrance in your amateur station contest.

Max Clinch Enjoys His Wireless Outfit Thoroly.

My aerial is of the "L" type, 300 feet long, 65 feet high, composed of four strands of antenium wire, spaced 2½ feet apart.

My receiving set consists of Murdock receiving transformer, variable condenser, crystaloi detector with cohering inductance, fixed condenser and 2,000-ohm Brandes 'phones.

My transmitting outfit includes a New York spark coil, spark gap, condenser, key and 12 batteries.

I have no trouble in getting Key West and can hear Arlington 20 feet from 'phones. I get most of my ideas from *The Electrical Experimenter* and could not afford to be without it.

MAX CLINCH.

Lakewood, N. J.

Amateur News

Radio Experimenter Talks 600 Miles on 1,320 Watts.

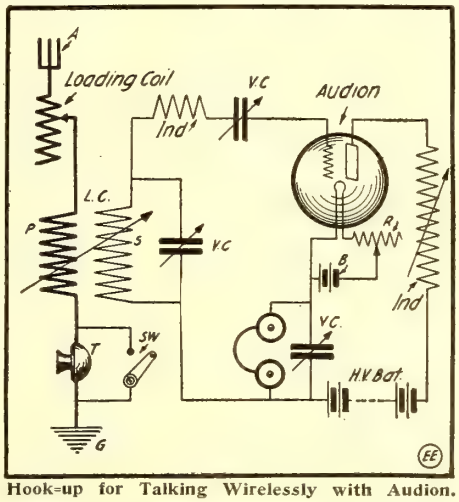
F. M. Corlett, wire chief of the Automatic Telephone Co., at his home at 1101 East Eighth street, Oak Cliff, Texas, recently talked by wireless to the Christian Brothers' College in St. Louis. Mr. Corlett has a regulation wireless apparatus erected in his back yard which he has but recently completed.

Mr. Corlett talked to St. Louis, a distance of 600 miles, with 1,320 watts of energy, which is considered unusual. Radio engineers generally figure 10 watts to a mile, which would have given Mr. Corlett a range of only 132 miles.

He picks up the time signals from the station at Arlington, Va., and often "listens in" on powwows between the United States transport "Buford" and some Gulf of Mexico neighbor.

Radio Club of America Meeting.

Several interesting papers were delivered at a recent meeting of the Radio Club of America, held at Columbia University, New York City, Mr. Emil Simon, a noted radio engineer, read a paper on Professor Pupin's testimony in a wireless suit between the Marconi and the Telefunken Companies. He expressed his ideas lucidly on the whole subject.



Due to the present patent litigations, no discussion was permitted after the paper was read. Chairman George Elty, one of the engineers who installed the radio telephone apparatus at Arlington, described the system and methods involved in this wonderful radio engineering achievement. He stated that the received wireless telephone message was amplified and then brought back to N. A. A. on a line.

Mr. Sadenwater, radio inspector, described a method and gave a circuit for using a regular audion receiving set as a wireless telephone transmitter and receiver and he proved with this circuit that a distance of over a quarter of a mile can be readily covered, utilizing an ordinary audion bulb. The diagram of the connections is herewith reproduced and it consists of an ordinary Armstrong hook-up, with a telephone transmitter connected in series with the ground lead. It should be understood that the audion must oscillate before it will transmit any current. By placing a short circuiting switch around the transmitter, it is possible to receive messages with the same circuit.

Mr. Whitting, president of the Worcester Radio Club, of Worcester, Mass., described in a very simple manner the exact effects that take place in a complete radio transmitter employing a quenched spark gap.

Among the members who participated in the discussion were Mr. Pacent, vice-president of the club, and Mr. Greeley.

At the December meeting Mr. William Dubilier delivered a paper on the "Construction and Operation" of his well-known direct-current vibrating interrupter.

Hook-up for Talking Wirelessly with Audion.

RADIO CLUBS ATTENTION!

We are always pleased to hear from young Edisons and Radio Clubs. Send a write-up of your Club with photos of members and apparatus to-day to: Editor "Amateur Gossip" Section, The Electrical Experimenter, 233 Fulton St., New York City.

University of Pittsburgh Reopens Wireless Plant.

The University of Pittsburgh department of electrical engineering reopened its wireless plant for public communication recently. With the cooperation of the Radio Society of Western Pennsylvania, the wireless work during 1914 and 1915 was satisfactory and a number of interesting experiments were carried on. The plant is similar in design to the immense Government station at Arlington near Washington.

An extensive program is being prepared for the spring. A number of experimental tests are to be arranged with long distance stations. A plan is being arranged whereby many university stations throughout the country will be organized into a radio society.

A large correspondence was carried on with amateurs during the past season and it is expected this service may still be continued. The following program has been inaugurated and will be in force Wednesday and Saturday nights until further notice:

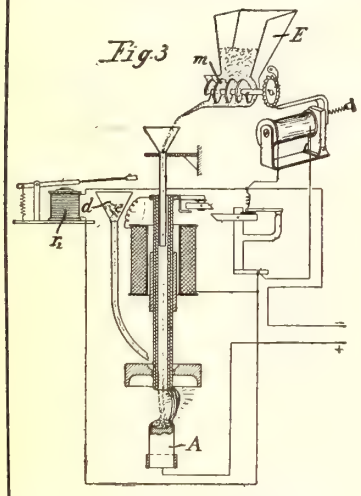
7.30-7.32—General call to all stations, call Q. S. T. signed Pitt; 7.32-7.50—Athletic results; 7.50-8—Items of interest to the public (12 words per minute); 8-8.10—News items at speed of 20 words per minute; 8.10-8.30—Special tests.

Scientific Class Organized in West Hoboken, N. J.

A Scientific Class has been organized in School No. 4, West Hoboken, N. J. Anthony Marino is president. The staff of research workers are John Saldavini, George Matterichi and John Reinert. We would be very pleased to correspond with similar organizations. All mail should be addressed to Anthony Marino, 511 Traphagan St., West Hoboken, N. J.

MEETING OF Y. M. C. A. RADIO CLUB OF VINCENNES, IND.

The Y. M. C. A. Radio Club of Vincennes held its first meeting at the Y. M. C. A., Tuesday, Nov. 30, and was well attended. The club has a very able instructor, who has worked as an operator on the Great Lakes. The following officers were elected: Walter A. Horner, first operator and president; John W. Surbaugh, second operator and secretary; Clinton E. Simpson, third operator and treasurer.



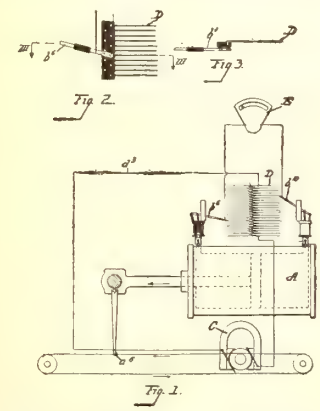
All radio correspondence from radio organizations and interested individuals should be addressed to the secretary, 912 Broadway. Those wishing to confer with the president will find him at 1225 North Second street.

LATEST PATENTS

Novel Electric Arc Lamp.

(No. 1,159,383; issued to Richard Holsten, assignor to Siemens-Schuckertwerke G. M. B. H.)

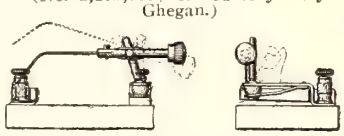
Electrical arc lamp employing for the lower electrode a suitable cup-shaped chamber A, into which a continuous and properly regulated stream of fine particles such as pure carbon (or any desired mixture of carbon with other substances which emit a strong light, such as metallic salts and the like), are fed. The arrangement is apparent from the illustration. The changing length



of the arc controls a magnetic clutch which feeds the pulverized carbon from a hopper E through the medium of a worm M. The metal salts may be injected separately through a hopper D, controlled by the magnet R^2. A very interesting patent.

Electrical Horsepower Indicator for Engines.

(No. 1,159,769; issued to Walter H. Hollstein.)

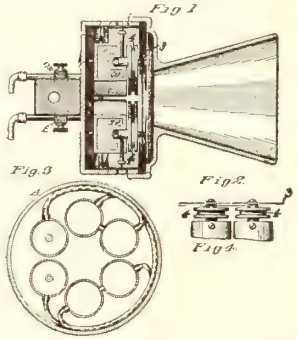


An electrical form of steam engine indicator for ascertaining the horsepower developed is covered in this patent. It appears to be quite feasible and a distinct advantage in this line. As perceived from the illus-

tration the piston rod or cross-head a^2 controls a belt secured to it and also to the shaft of a small dynamo C. The current from this dynamo passes through a resistance D. The changing steam pressures in the cylinder A, actuates the spring controlled rheostat arms b^6 and b^{10} by means of pistons. These rheostat arms slide over contact points as shown in Fig. 2, which lead to the different turns in the resistance coil D. The indications are given on a curve drawing, electric voltmeter E, which may be specially calibrated to indicate results in "horsepower" direct.

Holder for Crystal Detectors.

(No. 1,162,765; issued to John J. Ghegan.)

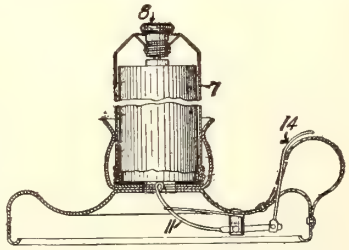


An improvement in wireless mineral detectors giving great ease of adjustment by virtue of the ball joint support of the vertical pillar, carrying the cat-whisker contact. The horizontal arm is also pivoted so as to be adjustable to any position desired. The contact wire can thus be swung up, down, or sidewise, also forward and backward.

Heavy Current Microphone.

(No. 1,165,255; issued to Charles D. Herrold and Emile A. B. Portal.)

A clever design of water cooled, heavy current microphone is here depicted. This patent covers the arrangement for utilizing a multitude of water cooled chambers on the end of each of which there is mounted the usual microphone chamber with carbon grains, etc., 4. These microphone units are all secured to a common metal diaphragm 3. The various water cooling chambers are so piped that water enters into the first one of the group and

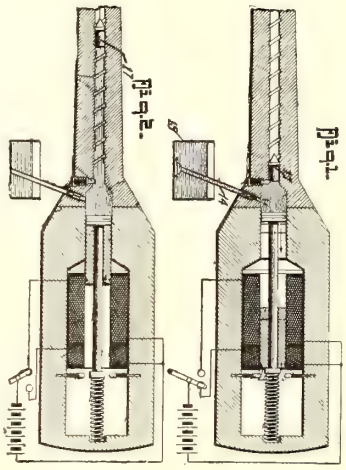


then passes consecutively throughout the entire number before it leaves the transmitter. The design should prove efficient if the size of the diaphragm 3 can be kept down within normal limits.

Portable Electric Lamp.

(No. 1,166,003; issued to Adolph C. Recker, assignor to Waterbury Mfg. Co.)

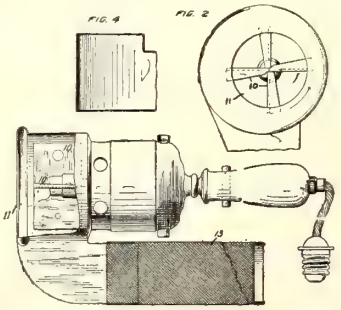
This patent relates to portable electric lamps, particularly of the candlestick variety. Flashlight battery of the ordinary type fits within a shell or chamber 7. The flashlight bulb is seen at 8, and the circuit from the battery is completed through a switch 11. This switch



blade is pushed against the end of the battery by a convenient thumb-actuated pin, pivoted in the manner shown. The best feature is that of the control switch.

Electro-Hydraulic Gun.

(No. 1,167,178; issued to Rollie Calvin Hill.)

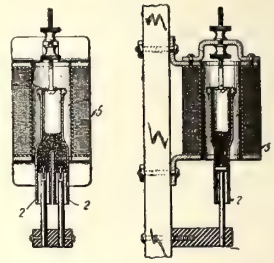


This patent covers the use of water or other fluids in combination with an electro-magnetic propelling mechanism for the ejection of projectiles from a cannon. The patent describes a double solenoid arrangement whereby a switch can be thrown so as to push or pull an iron plunger within the solenoid. When pulled backward, it sucks in the liquid from a tank 15 and when the solenoid is switched to the firing position, the plunger is rapidly propelled forward, simultaneously closing a check valve in the suction pipe 14, and ejecting the projectile 17, by virtue of the sudden rise in the hydrostatic pressure thus obtained.

An Electric Fly-Catcher.

(No. 1,165,712; issued to Frank Rea, assignor of one-half to Arthur M. Sheakley.)

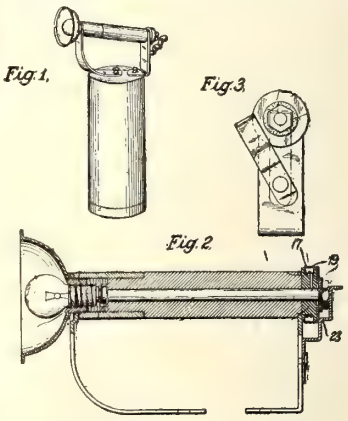
Another electric fly-catcher is here shown which involves the use of a small fan of special design. The metal chamber about the fan is of peculiar shape and terminates in a metal wire cage 13. The apparatus may be plugged into any lamp socket and consumes but little current. In service the flies or other



insects are drawn in through the opening 11. The fan blade appears at 10.

Coherer and De-Coherer.

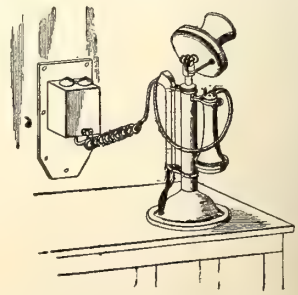
(No. 1,167,163; issued to Crosby Field Frank, assignor to General Electric Co.)



A reliable form of the filings type coherer suitable for transmission line signaling or for other purposes. The patentee mentions the use of granules of nickel specially prepared. The de-cohering is done by means of a magnet coil shown and by the special construction of the coherer tube. The granules when lifted by the magnet coil 5, will be dropped again unevenly, thus conducing to the regular and reliable resetting of the device. A constant and sharp critical voltage value can be obtained with this improved coherer it is claimed.

Electric Hand Lantern.

(No. 1,163,887; issued to Charles F. Burgess, assignor to C. F. Burgess Laboratories.)



An ingenious electric lantern attachment suitable for use with standard dry cells is here shown. The inventor provides a small rheostat in the end of the handle at 17, to protect the lamp when first used on a fresh cell. 23 is then thrown in contact with the shell 19, leaving the resistance in series with the lamp. As the battery begins to lose its energy, the switch is pushed into a vertical position and the lamp burns direct. This attachment can be adapted for use on two dry cells with a strap around them.

Telephone Cord Guard.

(No. 1,164,563; issued to Oadville Yates, Sr.)

The inventor of this attachment for taking up slack telephone cord to avoid abrasions, provides for the purpose a spiral wire spring with small hooks on each loop of the spiral. The telephone cord is wound around this spiral on the inside of it. When the 'phone is unmoved, the spiral appears as in the illustration, but when the 'phone is

moved, it expands. A guard is also indicated for protecting the cord.

COPIES OF ANY OF THE ABOVE PATENTS SUPPLIED AT 10c. EACH.

Phoney Patents

Under this heading are published electrical or mechanical ideas which our clever inventors, for reasons best known to themselves, have as yet not patented. We furthermore call attention to our celebrated Phoney Patent Offizz for the relief of all suffering daffy inventors in this country as well as for the entire universe.

We are revolutionizing the Patent business and OFFER YOU THREE DOLLARS ($3.00) FOR THE BEST PATENT. If you take your Phoney Patent to Washington, they charge you $20.00 for the initial fee and then you haven't a smell of the Patent yet. After they have allowed the Patent, you must pay another $20.00 as a final fee. That's $40.00 ! ! WE PAY YOU $3.00 and grant you a Phoney Patent in the bargain, so you save $43.00 ! ! When sending in your Phoney Patent application, be sure that it is as daffy as a lovesick bat. The daffier, the better. Simple sketches and a short description will help our staff of Phoney Patent examiners to issue a Phoney Patent on your invention in a jiffy.

PHONEY PATENT OFFIZZ

No. 40° 15' 7" N E by E. **Patent Applicated Feb. 30, 1916.**

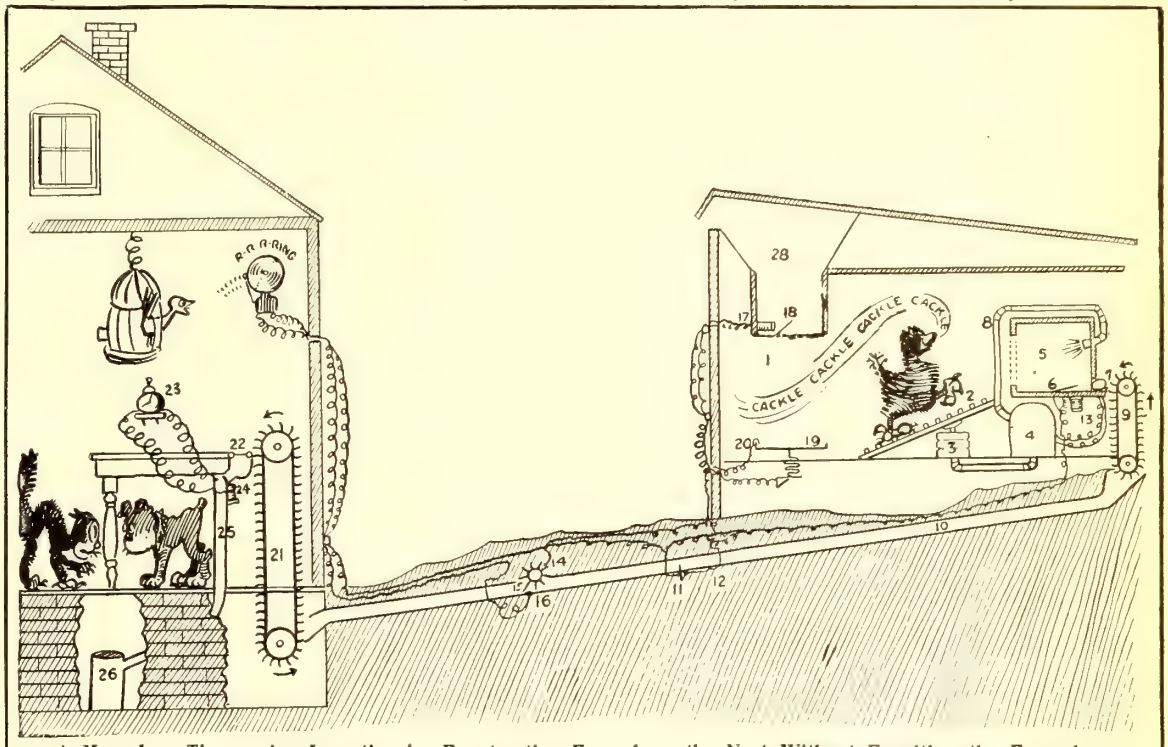
THE ELEGGTRICAL EGG EGGSTRACTOR

Be it a secret to all:

That I, Egg S. Natcher, of Yolkville, in the State of Remorse, have devised certain improvements worthy of notice by egg swipers who desire to eggstract the eggs from a nest without eggciting the eggmakers.

The attached specifications and drawing expose all the inards of the machination and lay bare the devilish details of my method of coercing the feathered bipeds to deliver up their contraband goods without the necessity of declaring a blockade.

Considering the details of this nightmare, at 1 is shown an ediffice known as a hen house, named after the inhabitants who abide or reside therein. The chicken on becoming ambitious mounts corrugated pathway 2 leading to the nest. The weight of her wait on the board compresses bellows 3 and thus pumps air into tank 4 and is there stored. The hen then passes into the boudoir 5, at which point, dear reader, we gently draw the curtain.



A few minutes and the click of the switch 6 is heard as it is pushed onto contact 7 by the egg. The closing of the switch releases a stream of compressed air from tank 4, which flows through pipe 8 and gently but firmly makes it evident to the hen that her presence is no longer required.

The lonesome and unloved egg rolls then onto conveyor 9 and thence through underground tube 10. With a rising and falling, sinuous motion it approaches switch 11 and without warning swings it onto contact 12 and then continues its explorations. The switch 11 cuts off compressed air supply and resets switch 6 by means of electro-magnet 13 and also rings bell in house to warn the reception committee of the approach of their guest of honor.

The egg, then, egglike rolls against the wheel 14 and turns it one notch. On the wheel is arranged a projection that as the wheel completes a revolution makes contact with 16. Instantly electro-magnet 17 acts, opens door 18, allows feed to flow from hopper 28 into pan 19 which, on becoming full, settles gently down on the spring, opens contact 20 and thus hopper door is closed by its own weight.

But to follow the egg. It is rolling along, then suddenly lands on conveyor 21 and gets a raise up, up and over into receiver 22. It rests here awhile from its labors but is quickly awakened by the alarm clock, which closes a circuit, energizes magnet 24, and drops it down through tube 25 into the tomb 26, wherein it is stored. The alarm advises the house of the arrival of the newly born.

In testimony hereto, thereof, I attach my handcuff and seal-packerchief this yesterday of to-morrow in the City of Yolkville.

A Marvelous Time-saving Invention for Eggstracting Eggs from the Nest Without Eggciting the Eggmakers.

(Signed) Egg S. Natcher,
By his attorney,
Geo. M. Gray,
Needham, Mass.

Witnesses: Sol. Idivory, Hen Nery, R. O. Oster.

THE "ARLINGTON" BUG?

This is an introduction to one of Dame Nature's curiosities and mysteries! X— ??

The other night I was awakened by a shrill —. .— .—, and thought I must have dreamt it; but I heard it twice before going to sleep. The next morning we found a large green winged insect which I suspected of working its "transmitter" on Arlington's call. (N. A. A.)

I would not believe this story myself, if someone else told it, but would like to know if anyone else among the *Electrical Experimenter's* readers has had the same experience.

(*If the "green" bug had an "antenna" it probably was tuned to the tune of "N. A. A.," which caused it to sing when Arlington was sending, what?—Ed.*)

Contributed by

PAUL F. SHNEY.

HEARD OVER THE TELEPHONE?

Pat was called into court to testify to a talk that he had had with the defendant in a civil suit, and everything went along as swimmingly as a flock of bullfrogs until the lawyer attempted to bring out the important points of the conversation.

"Now, then, Pat," said he, encouragingly, "please tell the court what you and the defendant talked about."

"Yis sor," answered Pat, willingly. "We talked about 15 minutes."

"No, no, no!" interposed the lawyer. "I mean what did you and the defendant talk over?"

"Yis, sor," was the calm rejoinder of Pat. "We talked over the tilephone, sor."

THE TUNELESS SOLO.

Signor Marconi, the wireless inventor is likely to prove of great value to his country in the present crisis.

An amusing story is told about a reply that the celebrated inventor once made to a lady who mistook him for his equally famous compatriot, Mascagni, the composer.

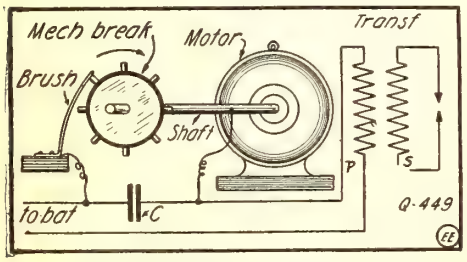
"Oh," she said, gushingly, "I'd love to hear you play your beautiful 'Intermezzo!'"

"Madam," replied Marconi gravely, "I'll do it with pleasure if you've got a wireless piano."

QUESTION BOX

This department is for the sole benefit of the electrical experimenter. Questions will be answered here for the benefit of all, but only matter of sufficient interest will be published. Rules under which questions will be answered:

1. Only three questions can be submitted to be answered.
2. Only one side of sheet to be written on; matter must be typewritten or else written in ink, no penciled matter considered.
3. Sketches, diagrams, etc., must be on separate sheets. Questions addressed to this department cannot be answered by mail.



WATCH DEMAGNETIZER.

(448.) William H. Kelly, Holyoke, Mass., wants to know the number of feet of copper wire required to build a 110-volt a.c. watch demagnetizer.

A. About 1,000 feet of No. 30 B. & S. gauge copper wire would be necessary. This should be wound on a brass form or bobbin, having an opening large enough to admit a watch. The length of the spool should be about two inches.

TRANSFORMER.

(449.) C. L. Bauman, Cherokee, Ia., asks whether he can employ a 16-cell battery plant of 32 volts and 120 ampere hour capacity to operate his flexible step-up transformer.

Mechanical Break for Spark Coils.

A. The transformer can be successfully operated from this plant by employing a suitable interrupter. This interrupter may be of the independent magnetic or mechanical break type. The accompanying illustration gives the connections for the interrupter and transformer.

LOUD SPEAKING RECEIVER.

(450.) Buran Studdard, Leavenworth, Kan., asks us several questions which he would like to have answered. 1. The cost of a telegraphone, as described in the June, 1915, issue of *The Electrical Experimenter*. 2. The price of a loud speaking telephone receiver.

A. 1. The cost of the experimental telegraphone would be in the neighborhood of $75, although this amount would be reduced if built by yourself.

A. 2. A loud speaking telephone receiver would cost $25 of the type to be used in place of an ordinary 75 ohm receiver. A plain independent type loud speaker complete with microphone and rheostat for battery circuits costs about $5.

AUDION BULBS.

(451.) Edward Law, Clarksburg, W. Va., wants to know: 1. Whether a 6-volt 40-ampere hour storage battery will operate an audion as well as six dry cells. 2. The average life of the tantalum filament of the audion bulb. 3. The length of time such a storage battery will last, if used but two hours per day in connection with the audion.

A. 1. The 40-ampere storage battery will successfully operate the audion bulb and, in any case, it will be more satisfactory than the dry cells for this work.

A. 2. The average life of the tantalum filament in the audion is about 400 hours, but this can be lengthened by using the filament at a lower incandescence, i.e., by using a rheostat.

A. 3. Your storage battery will operate the audion bulb for about 40 days if used but two hours each day, without recharging.

WIRELESS BOOKS.

(452.) Fred W. Jameson, Leavenworth, Kan., asks for information on the following: 1. The title of a book on the construction of high grade wireless apparatus. 2. Whether the primary of a loose coupler should be wound with stranded wire, and if the loading coil used in connection with the coupler should be wound with the same size wire. 3. The location of an antenna in regard to a high voltage transmission line.

A. 1. We can recommend two excellent books covering this subject, which are published by The Experimenter Publishing Co. They are "How to Make Wireless Sending Apparatus" and "How to Make Wireless Receiving Apparatus," which are sent prepaid for 25 cents each.

A. 2. The primary of a high grade loose coupler should be wound with stranded wire. While the loading coil may be wound with the same size wire as the loose coupler, it is better to use a larger size wire for this instrument.

A. 3. It would be all right to place a 200-foot aerial directly over and at right angles to the 2,300-volt line. It is also advisable to use means to prevent accidents resultant from having the antenna fall on the transmission line, which would be dangerous in the extreme.

WAVE LENGTH OF COUPLER.

(453.) Leonard Mabbott, Aberdeen, S. D., wishes to know: 1. The wave length of his loose coupler. 2. The reason he can hear a certain station with one hook-up and not with another. 3. The positions of the slider of a loose coupler when it is at its lowest and highest capacity, respectively.

A. 1. The maximum wave length that can be obtained from the loose coupler you describe is 1,800 meters.

A. 2. The reason for your not being able to hear the amateur station you mention with the loose coupler circuit is that the wave length is longer than the transmitting wave from the other station, but this can be remedied by connecting a variable condenser in series with the ground.

A. 3. When the sliders are at the starting end of the winding of a loose coupler, the instrument is being used at its minimum capacity; conversely, when they are at the opposite end of the winding the maximum wave length capacity is reached.

ANTENNA QUERIES.

(454.) George D. Hankins, Yorktown, Ind., 1. Sends us a diagram of his antenna, and wishes to know whether a better type could be designed with the same amount of wire. 2. The efficiency of the loose coupler described in the September, 1915, issue of *The Electrical Experimenter*.

A. 1. A straight four-wire antenna would be more efficient for transmitting than any other form of aerial, but the same amount of wire used in a single line would make a far more efficient antenna for your receiving purposes than most other types.

A. 2. Although this loose coupler with both windings wound with No. 26 wire would be almost as efficient as if wound with No. 24 and No. 28 wire respectively, yet it is advisable to have the windings of different sizes of wire. This depends upon the type of detector employed, i.e., whether potential or current actuated.

PROBLEMS IN ELECTRICAL WORK.

(454A.) Jas. A. Davis, Pittsburgh, Pa., sends us several electrical problems: 1. How many amperes will a 22 h.p. dynamo produce, the output of which is 120 volts? What is the resistance? 2. A relay has four windings of 10, 20, 25 and 80 ohms connected in parallel. What is the resistance of the relay? 3. If .08 amperes flows through a keyboard lamp, what is the difference of potential?

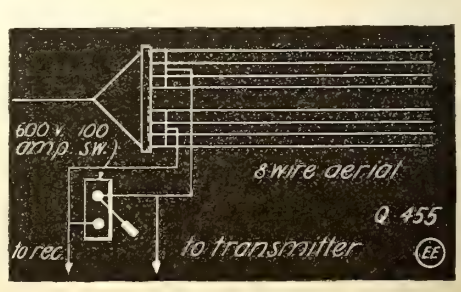
A. 1. This dynamo will produce 136.7 amperes. The resistance is .087 ohms. These results were obtained by multiplying the 22 h.p. by 746 watts and dividing the product by 120 volts, which gives the amperes. The resistance is obtained by substituting the values in the following formula:

$$R = \frac{E}{I}$$

R in ohms, E in volts and I the current in amperes.

A. 2. The answer to this problem is 4.9 ohms. This result was obtained by substituting the values given in this formula:

$$R = \frac{1}{\frac{1}{r} + \frac{1}{r_1} + \frac{1}{r_2} + \frac{1}{r_3}};$$

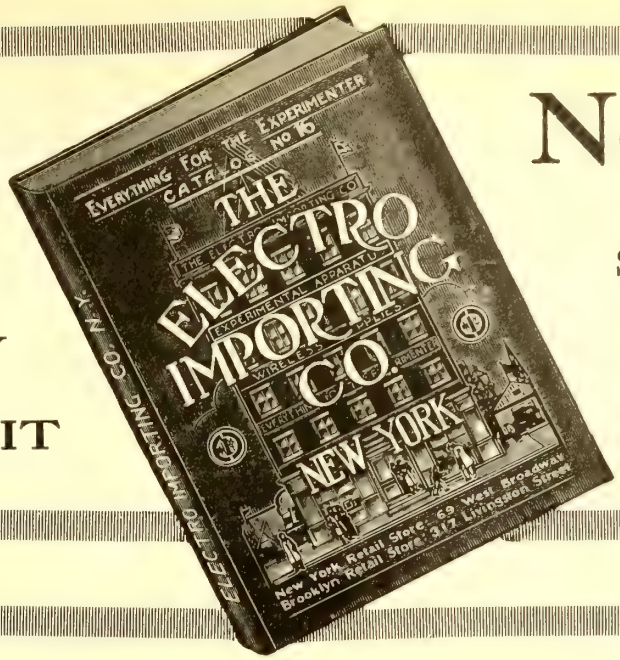


where r and r_1, etc., stand for the given resistance values.

A. 3. We cannot say what the difference of potential is as you do not state the resistance of the circuit. It is necessary in order to obtain the difference of potential of any circuit to give both the current and resistance.

PUMP USED FOR GROUND.

(455.) Experimenter, Jackson, Mich., wishes to know: 1. Whether a pump could be used for a ground. 2. A diagram for an eight-wire aerial constructed in such a



(*Continued on page* 650.)

Hook-up for Eight-Wire Aerial, with Change-Over Switch.

Audion "B" Batteries—50 Volts!!

FOR THE NEW MODEL AUDION DETECTORS

THE ELECTRO-SET COMPANY announce the development of a new, high potential battery for Audion Detectors.

These batteries have been developed for us in the most complete laboratory of its kind in the world.

They are especially designed for long shelf life and voltage maintenance and are a long step forward over the old makeshift flashlight batteries formerly used for the purpose.

Electro-Set Audion "B" batteries will not only increase the efficiency of these splendid wave detectors, but will also prove a considerable saving over the old type, both in initial cost and maintenance.

The open circuit potential of these batteries is about 50 volts; one Electro-Set Audion "B" battery replacing 12 flashlight batteries.

The new model Audion Detectors have been reduced in price and are no longer furnished with batteries of any description.

Our new "B" batteries will, therefore, be a welcome product to the trade.

They are recommended over any other form of battery for the purpose

Price, each, 50 volts tested and guaranteed.....**$3.50**

Shipping weight 8 lbs.

NOTE: Electro-Set Audion "B" batteries are designed only for Audion use. They are not to be used for any other continuous duty.

Why Buy Minerals on a Gamble?

The least expensive and the *most important* part of your wireless equipment is the mineral in your detector.

An expensive receiving equipment will do only mediocre work if the detector is not sensitive. *Don't Neglect This Important Point.*

READ WHAT OTHERS SAY!

A few letters selected at random from our files.

Milan, Ohio.

The Arlington Tested Galena Crystal that I bought of you some time ago has given the best service, by far, of any crystal I have yet used.

Yours very truly, RALPH H. SAYLES, Jr.

N. Manchester, Ind.

I received your N A A Tested Galena. It is more satisfactory than advertised. Yours truly, EUGENE SMITH.

Purcell, Okla.

I received the N A A Minerals last week, and I want to tell you that better results have been obtained with them than with any other.

Yours truly, JACK GILLETTE.

It costs mighty little to get extremely sensitive minerals. But it requires caution. Look carefully where you buy. To be *sure* accept only *Electro-Set Wireless Minerals*. Every package marked thus

GENUINE ELECTRO-SET MINERAL

Look for the Signature

J. S. Newman PRES.

THE PRICES ARE HIGHER.

They have to be. Our buyers scour the world for these supremely good minerals—but remember, after all, that even Electro-Set Minerals are not too high priced for the smallest pocketbooks.

ARLINGTON TESTED MINERALS
INDIVIDUALLY PACKED AND TESTED.

N A A Galena, each crystal carefully tested by experts for distant stations. Individually wrapped and packed in wood containers. Postage paid.....25c.

N A A Silicon, individually tested, wrapped and packed. Postage paid.....25c.

N A A Zincite Couple, specially selected, tested and packed. Extremely sensitive. Postage paid.....50c.

ELECTRO-SET ARLINGTON SILICON

Triple "A" Grade Electro-Set Minerals
Packed in convenient one, four and sixteen ounce cartons.

These ultra-sensitive minerals are the only ones you should buy. Look for the original signature on the wrapper.

PRICE LIST OF TRIPLE "A" GRADE MINERALS

	1-oz Can	4-oz Can	16-oz Can
Galena	25c.	60c.	$1.50
Silicon	25c.	75c.	2.50
Bornite	25c.	75c.	2.50
Copper Pyrites	25c.	60c.	1.50

Carborundum	25c.	60c.	1.50

Zincite, Pure, per ¼ oz. Can, 50c. **Prices are prepaid**

Dry Storage Cells

CAN BE RECHARGED 300 TIMES.

One charge has energy of **seven** dry cells. 400 amperes on short circuit.

These cells are the newest development in the storage battery field.

They may be used in any position, are easy to transport, cannot spill or corrode, and are ideal for experimental work of any description.

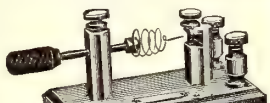
Each cell develops two volts in full charge and has a capacity of 20 ampere hours. They are convenient in shape being about of the same dimensions and size as an ordinary dry battery.

The price is so low that any experimenter can afford them. In the long run, they are much less expensive than dry cells and any garage will charge them at very low cost.

If you have 110 volt direct house current, these batteries may be charged by **merely connecting them in series with 1-100 watt lamp** or 4-25 watt lamps in multiple

USES:

Audion detectors (filament batteries).
Portable and Stationary Wireless Sets.
Automobile Lighting.
Experimental Work.
Hand Lanterns.
Stationary Engine Ignition.



In fact, these batteries may be used in place of any other type of storage cell.

Allow 1 cell for every 2 volts required (i.e., for 6 volts use 3 cells, etc.) Shipping weight 5 lbs.

Price, each.....**$2.00**

SEND FOR CIRCULAR.

The Mineral Detector

We have greatly improved our popular No. 1603 Detector with no increase in price.

This type mineral detector is the most convenient and easily adjusted ever produced.

In connection with our famous super sensitive minerals, it is as sensitive a detector as you could desire.

Handsome in appearance and generous in size.

The cat whisker wire is easily removed, and replaced in the **Special Chuck Holder.**

Minerals are readily inserted and are firmly held in good contact. Any degree of pressure may be brought to bear on the mineral.

Price, postage paid.....**$1.25**

Dept. 510 *The* **Electro-set Co.** **1874 E. 6th St. Cleveland, O.**

SEND 4c. IN STAMPS FOR CATALOGUE

QUESTION BOX.

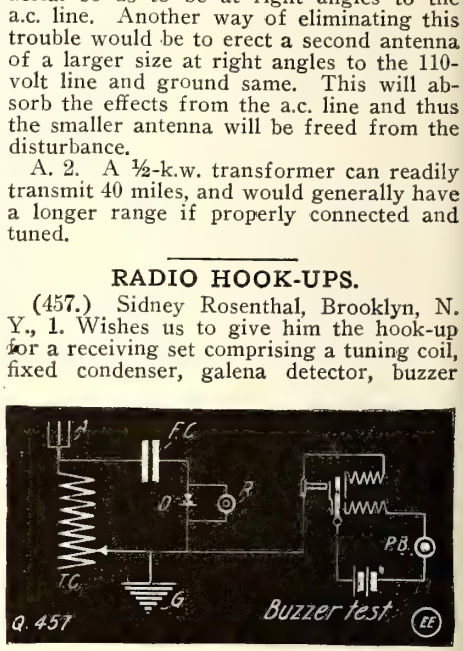
(*Continued from page* 648.)

manner that four wires may be used for transmitting and the whole number for receiving.

A. 1. The pump can be successfully employed for a ground.

A. 2. The diagram herewith shown gives the constructional details of an eight-wire aerial to be used in the manner you specify.

ANTENNA EFFECTS.



(456.) John Bedford, Morsemere, N. J., desires to know: 1. Whether a 110-volt a.c. line would affect the reception of messages through an antenna placed four feet distant. 2. Whether a ½ k.w. transformer would transmit 40 miles.

A. 1. The 110-volt a.c. line would affect your receiving antenna if they are parallel to each other. You could eliminate this trouble by changing the position of your aerial so as to be at right angles to the a.c. line. Another way of eliminating this trouble would be to erect a second antenna of a larger size at right angles to the 110-volt line and ground same. This will absorb the effects from the a.c. line and thus the smaller antenna will be freed from the disturbance.

A. 2. A ½-k.w. transformer can readily transmit 40 miles, and would generally have a longer range if properly connected and tuned.

RADIO HOOK-UPS.

(457.) Sidney Rosenthal, Brooklyn, N. Y., 1. Wishes us to give him the hook-up for a receiving set comprising a tuning coil, fixed condenser, galena detector, buzzer

Simple Wireless Receptor-Circuit With Tuning Coil.

test and receivers. 2. Also if two persons can operate separate receiving sets from the same aerial.

A. 1 The illustration herewith shows the connections for the instruments you mention.

A. 2. It is possible for two receiving sets to be operated from the same aerial, but the energy received in either one set would be considerably reduced, unless the wave lengths utilized are quite different in value.

ROTARY GAP.

(458.) Rudolph Wensko, Cleveland, O., inquires: 1. Whether a rotary gap will work on a ½-k.w. transformer coil. 2. At what speed must an amateur be able to send and receive signals in order to obtain an amateur license. 3. The manner in which the taps of a Navy loose coupler are connected, so that one turn at a time may be obtained.

A. 1. A rotary gap can be successfully operated on a ½-k.w. transformer coil, but a quenched gap is best.

A. 2. An amateur must be able to receive and send at least 10 words per minute to obtain a government radio license. He must also be familiar with the technical

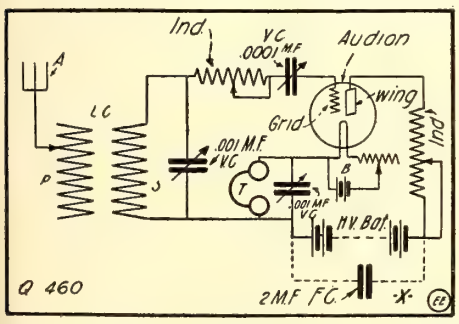
details of radio apparatus to a fair extent.

A. 3. A description of the Navy type loose coupler was published in the September, 1915, issue of *The Electrical Experimenter*, which included the method of connecting the taps so as to obtain single turns at a time.

RADIO TELEPHONE.

(459.) Edward C. Jones, Jr., Fairmont, W. Va., wishes information as to: 1. Whether there is an inexpensive wireless telephone set available that can transmit three miles. 2. If it is possible to construct a wireless telephone with a 1-inch spark coil, microphone, etc., and obtain good results. 3. Whether a dictaphone, of the type described in a recent issue of *The Electrical Experimenter* could be used as an amplifier.

A. 1. As far as we know there is no cheap wireless telephone for the use of the amateur on the market, but we would suggest that by writing the Radio Telephone and Telegraph Company, of New York City, you would no doubt be able to find out if any such telephone is for sale at a price within your reach.



A. 2. It is possible to construct a simple wireless telephone outfit by employing a 1-inch spark coil, microphone, etc., but the results would be very poor on account of the unequal sparking rate of the gap which gives irregular sounds at the receiving end, and also due to the low frequency of the sparks. Although the results may be bettered by using several spark coils connected in parallel so as to form a multiple sparking gap, which will increase the sparking rate of the complete device of course. Even then the speech at the receiving end will not be clear. This outfit will transmit over a short distance of, say, about a mile or more. A very short spark gap must be used, about the thickness of the paper of this page.

DIAGRAM FOR UNDAMPED WAVE RECEIVER.

(460.) Reginald Pink, Bronx, N. Y., wishes us to give him the following information: 1. A diagram of an undamped wave receiver employing the audion. 2. The size of wire employed in winding the various coils. 3. Whether the Electro Importing Co.'s Mignon Vario-Selective coupler will receive undamped waves with an audion.

A. 1. The accompanying illustration gives the proper hook-up for the reception of undamped waves, employing the audion. The capacities of the various condensers are given. Condenser X is optional but is strongly recommended.

A. 2. The secondary loading coil is wound with No. 28 B. & S. copper magnet

Audion Circuit for Reception of Undamped Waves.

wire on a tube 4 inches diameter, 30 inches long; while the winding of the "wing" coil is of No. 30 B. & S. copper magnet wire wound on a similar size tube.

A. 3. The coupler you mention may be successfully employed for the reception of

Multi-Audi-Fone

The new wonder in the wireless world. It increases the Audibility 1,500 Times

We Guarantee Everything We Make! We Guarantee Everything We Say!

Every County Attorney should have one of our **Detectorphones** if he wants to know what offenders are plotting.

EveryHotel should have some rooms equipped with our **Detectorphones** in order that they may detect and eject objectionable characters.

Every Business Man should have one of our **Detectorphones** if he wants to know which of his employees is planning and plotting to bring on a strike.

Every Detective should have one of our **Detectorphones** if he wants to succeed, for you can tell just what the fellow you are after is saying even in the faintest whisper, forty feet away, in the garret or in the cellar.

Price, $35.00.

UN-DAMPED-WAVER.

Do you want to get Nauen, Hanover, Sayville, Tuckerton, San Francisco, Honolulu and the Naval Arc Stations on just a good, ordinary Aerial? Do you want to become thoroughly familiar with the action of the new valve circuits? Then you want our Un-Damped-Waver.

Price, $100.00.

TWO STEP MULTI-AUDI-FONE.

Are you a jeweler? Do you want Arlington time shouted to your visitors every day at 12? Are you a teacher of wireless? Do you want your 500 students to read the signals? Both of you men should have our Two Step Multi-Audi-Fone with its Trumpet Horn with specially wound Head Set.

Price, $75.00.

MULTI-AUDI-FONE.

Do you want to get a lot of stations you do not hear now? Do you want to get those you now hear only faintly and unsatisfactorily, clear and strong, often even audibly? Do you want to enter a new Wireless World? Then you want our Multi-Audi-Fone.

Price, $30.00.

TELEPHONE VOICE MULTIPLIER.

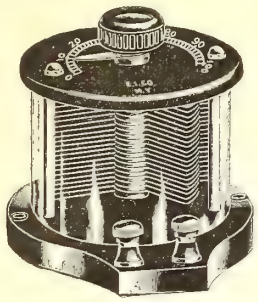
Are you hard of hearing? Are your Telephone lines or connections poor? Are your long-distance calls weak? Do you want to know exactly what the fellow at the other end of the line is saying? Then you want our Telephone Voice Multiplier.

Price, $15.00.

Everyone of these instruments is *one hundred fold better than any other instrument of its kind.*

If you don't believe it—try them.

If after a ten days' trial you are not surprised and more than satisfied—we will return your money.



Will any one else do this? **Tear this out and ask for information about the instrument that interests you by writing its name here**

Send for circular to-day

LA SALLE LIGHT COMPANY, 134-136 N. La Salle St., Chicago, Ill., Opposite City Hall

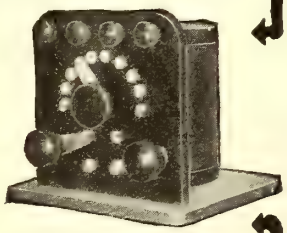
NEW WIRELESS WONDER

THE INSTANT RADIOGRAPH

Greatest invention of the Age. The result of years of experimentation.

Abolishes detector troubles and adjustments—
No more delays—no more lost time and messages

Pick up your receivers any time, Summer or Winter, in any atmospheric conditions and—



You Can Receive Instantly Without Any Adjusting

3,000 miles is latest record of the Instant Radiograph.

It is wonderful, but true, you cannot get the Instant Radiograph out of adjustment no matter how you knock it about. Try it yourself, hit it with a hammer while in use.

Vibrations, jars, knocks cannot affect it as there are no fine adjustments to make—no batteries—nothing to wear out—no operating expense whatever.

INTRODUCTORY PRICE FOR MARCH **$3.00**

Cut ¼ Actual Size.

The Instant Radiograph is more efficient than any detector on the market, as there is nothing to adjust.

The Instant Radiograph is beautifully and solidly constructed on a heavy base of hard rubber 4 x 4 inches square with rounded corners and 4¼ inches high; binding posts are made of non-corroding metal, heavily silver plated, and have heavy rubber-covered thumb screws, preventing current leakage. **All contacts are large, non-corroding, heavily silver plated, of large size and will last a lifetime. This is a wonderful instrument of distinctive appearance that you will be proud to have in your wireless station.**

The Radiograph is the greatest recent invention in the Wireless field. Its value is priceless and as we want every professional and amateur operator on land and on board ships to use it, we have decided to make an introductory price of $3.00 for a limited time only. This is only one-third of the price at which it should be sold. Send your order at once. **Send for free Catalog E of the Instant Radiograph.**

You need this new book. "Radio Stations of the World." A complete authentic list of call signals of every public wireless station. Price, only 50c.

UNIVERSAL WIRELESS COMPANY, 19 East 32nd St., New York

This New Tuner Only $8.00

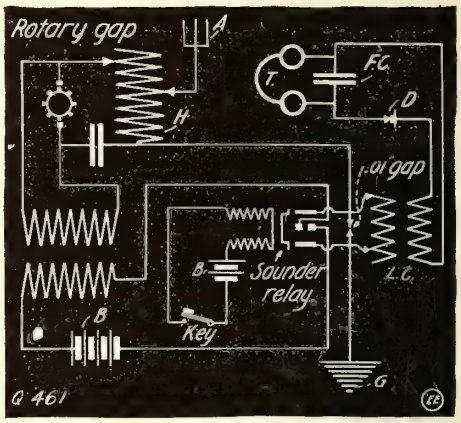
"Your New Receiving Transformer having 20 taps on the primary and 9 on the secondary is very efficient, and worth twice as much as the one with sliders, although that tuner does great work. Gordon F. Danforth, Syracuse, N. Y."

We also make a 10,000 meter tuner. Send 2-cent Stamp for Bulletin 107.

Just Out

Colby's Telegraph School
Auburn, N. Y.

undamped waves with an audion, with the addition of the inductances just described.



BREAK-IN SYSTEM.

(461.) Elmer C. Lundy, San José, Cal., asks: 1. The length of time for which an amateur license is issued. 2. What device will eliminate the flickering of the lights when operating a transformer on 110 volts a.c. 3. The connections for a satisfactory break-in system, using a rotary spark gap.

A. 1. An amateur operator's license is issued to cover a period of two years, while a station license is given for one year only. These licenses may be renewed by applying to the chief radio inspector of your district, sending him affidavits to the effect that the applicant's station has been in operation for the preceding six months.

A. 2. A kick-back preventer will sometimes help to eliminate the severe flickering of lights caused by the operation of a transformer on 110-volt a.c. lines, but a choke coil is invariably required in series with primary circuit.

A. 3. The illustration herewith shows

Break-in Hook-up for Radio Sending and Receiving Circuits.

the connections of a break-in system, including a rotary spark gap in the transmitter.

KITE AERIALS.

(462.) Ira Hull, Zenith, Kan., wishes advice: 1. As to the size of wire suitable for an aerial that is to be supported by a Malay kite. 2. The number of feet of wire which said kite can support. 3. The wave length that can be tuned with such an antenna, one loose coupler and one loading coil.

A. 1. No. 22 B. & S. bare copper wire can be used with success for the aerial supported by a Malay kite.

A. 2. The kite will be able to carry about 1,000 feet, although this length could be increased by using finer wire.

A. 3. The wave length to which you could tune with this outfit would be about 8,000 meters.

REGARDING WAVE LENGTHS.

(463.) Henry Gerke, Westwood, N. J., wants to know: 1. The wave length of W. C. C. 2. The wave length and the time at which W. H. B. sends "press." 3. Where he can obtain copies of (a) United States Naval Radio Regulations. (b) Regulations Governing Radio Communication. Act of Aug. 13, 1912. (c) Berlin International Radiotelegraphic Convention and Regulations.

A. 1. The wave length on which W. C. C. operates varies from 12,000 to 15,000 meters.

A. 2. The time at which W. H. B. usually sends "press" is 10.15 p.m., and the wave length on which he operates is 600 meters.

A. 3. The copies of these books can be obtained from the United States Printing Office, Washington, D. C.

TELEGRAPHONE TALKING HEAD.

(464.) Radio Amateur, Irvington-on-Hudson, N. Y., wishes us to tell him: 1. Can the armature of a telephone magneto be used in the construction of a telegraphone, if a hole is bored lengthwise through the center of it. 2. Is a pair of 1,000 ohm receivers more sensitive than a single receiver wound up 2,000 ohms.

A. 1. We do not believe that the armature of a telephone magneto can be used in the construction of a telegraphone head.

A. 2. A pair of 1,000 ohm receivers are more sensitive than a single receiver wound to 2,000 ohms. This is due to the fact that the two phones act on both ears simultaneously.

CHEMICALS.

(465.) K. Beymer, Dayton, O., wishes us to give him the name of a house where he may obtain chemical apparatus and chemicals.

A. Eimer & Amend at 211 Third avenue, New York City, should be able to supply your wants for chemical apparatus and chemicals. We would suggest that you write to them for prices and catalog. Also refer to our advertising columns.

SPECIAL ELECTRIC BULBS.

(466.) J. H. Kahler, Rochester, Minn., wants to know: 1. Where he can obtain special electric light bulbs. 2. Where he can have special mercury vapor arcs made. 3. Whether a variable condenser is better than a fixed type when it is used in shunt with wireless 'phones.

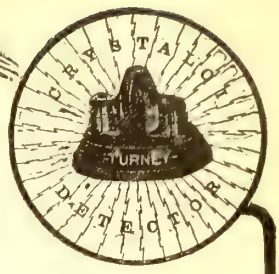
A. 1. For these bulbs we would refer you to General Electric Lamp Works, Harrison, N. J., who will doubtless be able to make them for you.

A. 2. These lamps could be built by the firm mentioned in Answer 1, or by the Cooper-Hewitt Electric Co., Hoboken, N. J. The latter company would probably be better able to do this work, as they make a specialty of manufacturing mercury vapor lamps.

A. 3. It would be far more advisable for you to connect a variable or adjustable condenser in shunt with the receivers than a fixed one.

TOOLS.

(467.) Godfrey S. Bloch, New York City, wishes to know what we consider the 12 most important hand tools used by a machinist.



A. The 12 most important tools used every day by machinists and electricians are as follows: Hammer, screw-driver, pliers, hack saw, hand drill, dividers, calipers, chisel, wrench, drill, blow-torch and vise.

INDUCTION MOTOR.

(468.) Ervin R. Musgrove, Longmont, Colo., asks several questions relative to induction motors: 1. About a motor to be operated on a.c. and having an armature composed of copper bars and laminated iron discs, but not fitted with any commutator or slip rings. 2. On the constructional details of such a motor. 3. The reason why different results are obtained when applying Ohm's law to a.c. circuits as compared to d.c.

A. 1. The motor you are interested in falls into the category of induction machines. No commutator or slip rings for conveying current from the outside or feed circuit to the armature winding are necessary as the armature or "rotor," as it is called, has currents induced in its short-circuited windings from the magnetized

5000 miles—
From Hawaii to Richmond, Va.—
with
CRYSTALOI

"On Dec. 23 I made what I believe to be a new record for the Crystaloi Detector. About 11 P. M. I heard the station at Lahaina, Hawaiian Islands, a distance of 5,000 miles. Heard the station four different times.
(Signed) RALPH J. ROBEY, 3314 Floyd Ave., Richmond, Va."

We Guarantee Every Claim Made for

CRYSTALOI

The Highly Sensitive, Permanent

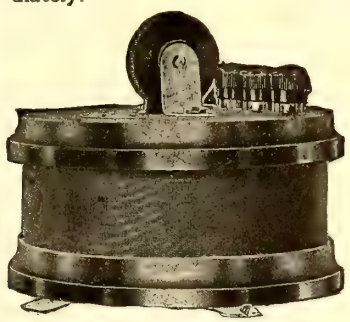
WIRELESS DETECTOR

What It Is

Crystaloi offers a large surface of highly sensitive mineral, which is brought into contact with a finely divided alloy—thus giving innumerable contact points. By rotating the cylinder the most sensitive spot is found immediately.

What It Does

Crystaloi will work under the heaviest static conditions—will not burn out—and with proper use will last a lifetime. With it every message will come in strong and clear.

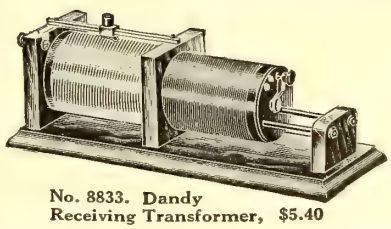


3 TYPES

Crystaloi.

TYPE O—Dimensions 2¼" x 1⅞". **Price, $3.50.** Postage 10c

TYPE AA—Equipped with a cohering inductance—Dimensions 4" x 3½". **Price, $6.00.** Mail. Wght. 2 lbs.



TYPE BB—Equipped with cohering inductance, fixed condenser, buzzer, test, batteries and control. Dimensions 7½" x5½" x 3½". **Price, $12.00.** Mail. Wght. 4 lbs.

TYPE AA. SUPER-SENSITIVE

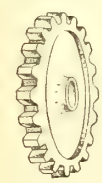
Reliable Supplies for Working Models

The following are just a few of the hundreds of items with which we can supply you. Every "Ideal" article is priced as low as is consistent with the quality. If you don't see what you need listed here, write us and tell us just what you want. Your order will receive our prompt and careful attention. Satisfaction guaranteed or money refunded.

PROPELLERS

accurately made of carefully selected wood. All types carried in stock from 6 inches up to 24 inches; made to order up to 7 feet.



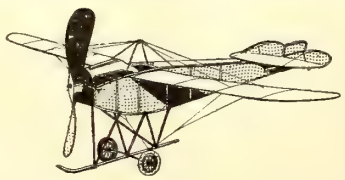
AXLES

Made of best quality steel rod. Being threaded on both ends and having nuts, they are very fine for CONNECTING TUNERS' ENDS AND LOOSE COUPLER SECONDARIES. Also made in brass at extra charge. 1/16 in. axles up to 6 in., 10c.; 7 to 10 in., 15c.; 11 to 15 in., 20c. 1/8 in. axles up to 6 in., 15c.; 7 to 10 in., 20c.; 11 to 15 in., 25c. Postage, 2c. extra.

"Ideal" Ball Bearing Propeller Shafts

These are perfect miniature non-friction Ball Bearing Shafts made precisely like the ball bearings used on large machines. They are perfectly constructed, have solid turned bearings and the finest steel balls and races. Flanges are drilled and ends of shafts are threaded and supplied with nuts and washers. *Flanges and upper ball-bearing cases are in solid piece of brass; not soldered and therefore unbreakable.*

No. 1—1/16 in. steel shaft. Weight 1.3 oz. Price, 50c.
No. 2—1/8 in. steel shaft. Weight 1.2 oz. Price, 60c.
Postage, 2c. extra.



GEARS

Clean cut, made right; run smoothly without noise or friction. Have 1/16 in. shaft hole but can be furnished with 1/8 in. hole at 10c. each additional. Postage, 2c. extra for each gear.

Size	No. of Teeth	Pitch	Price

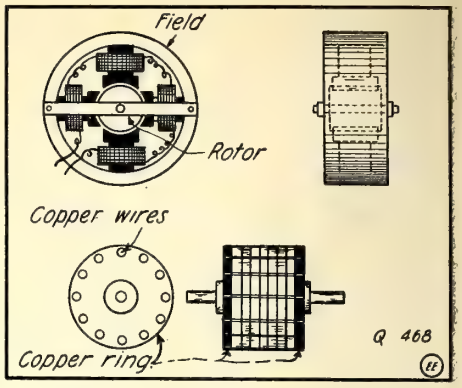
3/10 in.	10	40	.15
11/20 in.	20	40	.20
4/5 in.	30	40	.25

Build a FLYING Model War Aeroplane

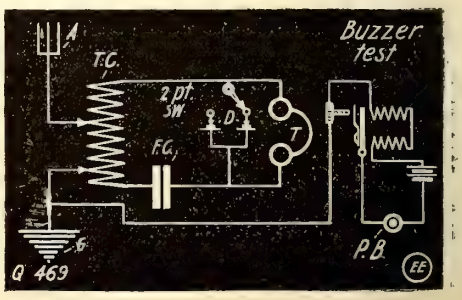


We can supply you with accurate scale drawings, instructions and all parts for the well-known types. For prices see our **interesting new 50-page catalogue.** All our experimenter's supplies are illustrated and described in this booklet. Write to-day for a copy. Price, 5c. postpaid.

SPECIAL ORDERS are promptly and carefully executed by our Mechanical Department. Submit us your drawings and specifications for quotations.

IDEAL AEROPLANE & SUPPLY CO. **76-82 West Broadway, New York**

field. This field is provided with a plurality of windings which are connected to the external source or exciting energy. Induction motors are supplied for either single



Assembly and Parts of Induction Motor.

or multi-phase circuits; the larger size motors being invariably supplied only for two or three-phase supply. Special windings and starting provisions have to be made for such motors, when adapted for use on single-phase a.c. circuits.

A. 2. Herewith the illustration showing the make-up of the induction motor. The rotating member consists of a number of soft steel discs mounted rigidly on a shaft in the usual manner. These are slotted similarly to a d.c. motor armature, but instead of being wound with coils comprising a large number of turns of wire, each slot receives a single, heavy copper rod or bar. Two heavy copper rings are placed on either rotor end and the copper bars in the slots are firmly riveted or soldered to these rings; thus there are provided a plurality of closed electrical circuits through the end connecting rings or discs and the inductor bars within the slots.

A four-pole field, made up of laminated annealed steel discs, is here indicated, but this is only used in most cases for small, single-phase fan motors and the like. In larger multi-phase motors the field has a large number of slots in the periphery of the rotor opening, which resemble almost identically the peripheral appearance of the rotor. In the stator slots appropriate windings are placed, consisting of coils of magnet wire. The rotor is moved or pulled around by the constantly changing rotating a.c. magnetic field set up by the stator windings.

A. 3. The reason that you obtain different results when using Ohm's law with a.c. circuit is that this law does not apply to a.c. circuits but only to d.c. circuits, due to the former manifesting marked capacity and inductive effects, which throw the current and voltage out of phase or synchronism.

Radio Receiving Hook-up.

THE TESLA PLANT.

(469.) Chas. W. Squires, Port Jefferson, L. I., N. Y., wants us to give: 1. The correct hook-up for a receiving set consist-

ing of two slide tuning coils, two detectors, silicon and galena, two-point switch to throw on either one, test buzzer for detectors and 75 ohm receiver. 2. The wave length of a two-slide tuning coil wound with 128 feet of No. 24 bare copper wire. 3. The location of Nikola Tesla's plant on Long Island.

A. 1. The illustration herewith given shows the proper connections for these instruments.

A. 2. The wave length of the tuning coil would be about 450 meters.

A. 3. This plant is located at Shoreham, L. I.

STEEL WIRE.

(470.) Edward L. Jewett, Sullivan, N. H., inquires of this department: 1. Where he can obtain long lengths of steel wire for use in the telegraphone, described in the June, 1915, issue of *The Electrical Experimenter*. 2. The difference between No. 32 steel piano wire and No. 32 B. & S. gauge wire.

A. 1. The steel wire used in the telegraphone can be bought in any desired length from most hardware stores.

A. 2. There is a difference between the diameter of wire designated as "No. 32 steel piano wire" and "No. 32 B. & S. wire," as the gauge used for measuring steel wire is not the same as that used for copper. The latter refers to the Brown & Sharpe standard gauge.

WIRELESS SCOUTS HONORED.

H. B. Thayer, president of the Western Electric Co., gave a dinner at the Hotel Astor recently in honor of the men who went to the far corners of the earth to receive the wireless telephone messages recently sent from Arlington, Va., and which were heard in Paris and Honolulu.

ELECTRICITY ON OCEAN LINERS.

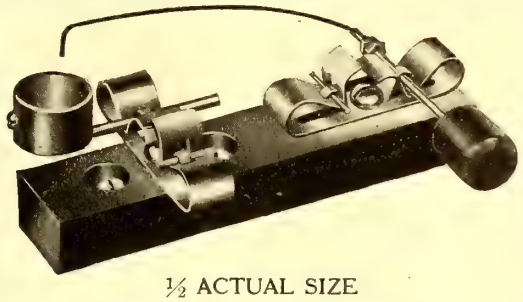
(*Continued from page* 611.)

in the house. There are two complete sets of apparatus, one for transmitting and one for receiving messages, the latter being placed in a sound-proof chamber in one corner of the house. There is also an independent storage battery and coil.

For submarine signaling apparatus is provided for receiving signals from submerged bells. Small tanks containing microphones are placed on the inside of the hull of the vessel on the port and starboard sides below water level and connected by wires to receivers situated in the port navigating room. The whistles are electrically actuated. The boiler-room telegraphs, stoking indicators and a number of auxiliary appliances, such as rudder indicators, clocks and thermostats, are also electrical, and the water-tight doors are released by electromagnets.

There are complete emergency circuits provided on all ocean liners. A separate and distinct installation is fitted in all parts of the vessel, deriving current from two

MARKO STORAGE BATTERY



TYPE 6WT8

Type	Volts	Amp. hr. capacity	Length	Width	Height	Special price to wireless engineers

"SOME" DETECTOR!

Absolutely the simplest and most practical Detector of the Cat Whisker type yet devised. Lacquered Brass for the metal parts and Polished Fibre for the base.

Has the usual merit of the "Winger" products.

Winger Electric & Mfg. Co.

711 So. Dearborn Street, Chicago, Ill.

Send two-cent stamp for Bulletin No. 3

Arnold Navy Type Loose Coupler

PRICE, $15.00

Owing to the peculiar construction and winding of this instrument it is possible for those desiring to hear the Arc Stations, to do so on this instrument. A special Hook-up is needed in order to get up to the wave length.

To those ordering an instrument such Hook-up will be furnished gratis.

It is as in the past the Right instrument to do all first class receiving with. Workmanship and material the best.

Send 2-cent stamp for Bulletin No. 3, which describes fully, also shows the finest line of Switch points, Rubber knobs and accessories on the Market.

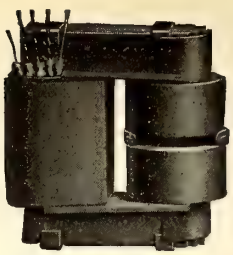
Positively unequaled for the money. Is 6" high, 6" wide, and 14" over all. Wound with Enameled wire, and has a very unique slider. Woodwork mahogany finished. Try one, you will not be disappointed.

5c. in stamps brings our 64-page illustrated catalogue, B-B-24. None otherwise.

F. B. Chambers & Co. 2046 Arch Street Philadelphia, Pa.

30-kw. sets and the 3,500-ampere-hour battery, so that in the event of current from the main dynamos being unavailable an independent supply is obtainable. Connected to the emergency circuit are about 500 incandescent lamps, fitted throughout all passenger, crew and machinery compartments, at the end of passages and near stairways; also on boat deck, to enable anyone to find the way from one part of the ship to the other. The following are also connected to the emergency circuit by means of change-over switches: Five arc lamps, seven cargo and gangway lanterns, wireless apparatus, boat davits, mast, side and stern lights and all lights on bridge, including those of navigating and chart rooms, wheel house, telegraphs, compasses and Morse signaling lanterns.

Very soon, it is freely predicted, ocean liners will also be driven by electric power, the Government having ordered such an electrical equipment from the General Electric Co. to drive the new battleship California, the largest in the world.



ELECTRICITY, THE BENEFICIENT.

(*Continued from page 619.*)

great aluminum industry with all its branches, for instance, is directly dependent upon the electric current for the production of the aluminum itself. Acetylene gas which is now used for so many purposes is obtained from calcium carbide, which is produced by means of the electric current. Carborundum, the well-known and widely used abrasive, is a product of one form of the electric furnace. The electric current is used in refining copper on a vast scale, for the purpose of purifying it and for the separation of the precious metals. Numerous other chemical industries are founded upon the use of the electric current. Fixation of atmospheric nitrogen for producing nitrates for fertilizing and other purposes is now accomplished on a large scale by means of the electric current, and it promises to become in time one of the vastest industries in the whole world. In fact, power plants of approximately half a million kilowatts, or more than three-quarters of a million horsepower, concentrated in a single station are now being considered for such production of nitrates. The time is coming when the whole world will be affected by this industry through food production.

Such a catacylsm as the complete cessation of all electrical activities would therefore result in such changes as greatly increased concentration of population around industrial centers, the city and the country would be pushed farther apart, many industries would be disorganized and some would be stopped completely, many great establishments would have to be reconstructed, types of buildings would be changed, methods of business would be modified, the producing capacity of individuals and of industries would be greatly reduced, methods of living would be modified, methods of transportation would be changed and for the worse; in fact, all conditions of life and fields of endeavor would be influenced, either directly or indirectly.

Myriads of times it has been said that "electricity is in its infancy," until people have come to believe that it is a perpetual infant like Buster Brown for instance, but it has now grown to robust stature and unostentatiously has assumed a goodly share of the world's burdens. Its efforts have been productive and not destructive. In this sense it has been one of the most beneficent agents of mankind. In Arabian Nights' parlance it is one of the good genii.

UNMOUNTED TRANSFORMER

You Can Get Results

with a small condenser and this transformer

It is a 1-2 K. W. size and is built on the same specifications as to material and workmanship, etc., as our big central station transformers.

Hundreds of stations are now using these transformers. This transformer gives you 13,200 volts.

Let us tell you how you can do part of he work yourself and get this transformer at a remarkably low cost.

PATENT ADVICE

Edited by H. GERNSBACK

In this Department we will publish such matter as is of interest to inventors and particularly to those who are in doubt as to certain Patent Phases. Questions addressed to "Patent Advice" cannot be answered by mail. Sketches and descriptions must be clear and explicit. Only one side of sheet should be written on.

FREIGHT CAR LOCK.

(47.) Elmer D. Gehman, Macungie, Pa., desires to have our advice on a freight car door lock which he has invented. He submits description and illustrations of same.

A. The idea to us seems novel and as far as we have ascertained by a careful examination of our files and reference books nothing like the idea submitted is in existence so far. We would, however, advise our correspondent to get in touch at once with a patent attorney to find out what has been done in the art before. It will only cost a small sum of money to get the references of other patents that have been obtained on such locks, and they perhaps will show our correspondent how to go about getting a valuable patent on the invention.

NON-REFILLABLE BOTTLE.

(48.) Ralph H. Zimmermann, Sutton, Neb., desires to know if there is such a thing as a simple and practical non-refillable bottle, and whether one is on the market and in actual use. He also wishes to know if it is worth while to spend time and money in the invention of such a bottle.

A. As stated before to another correspondent, several thousand patents have been taken out on non-refillable bottles, and as far as we are aware, there are not six being used at the present time. The ones that use them are mostly the liquor people, to whose interest it is to see that the bottle is not refilled after its contents have once been emptied.

We have stated the case clearly above and our advice to inventors of non-refillable bottles is that they should not waste a lot of time and money inventing one, as practically everything has been attempted in this art, and several very good ideas are in actual use to-day.

As far as we are concerned, there is no such thing as a non-refillable bottle, as any non-refillable bottle, no matter how well constructed, can be refilled if anybody really wants to do so.

We know of a case where an unscrupulous bartender removed the label of a liquor bottle, the brand of which had a very wide sale. After removing the label, a small hole about ⅛ in. in diameter was drilled into the bottle, and by using an ordinary suction pump the bottle could thus be refilled quite easily with an inferior brand. The small hole was plugged up with cement and the label again placed on the bottle. Consequently the non-refillable bottle could be refilled in spite of the fact that this was about the best bottle of this kind on the market. While such cases are of course infrequent, it still goes to show that where there is a will there is a way.

COMMUTATORLESS D. C. GENERATOR.

(49.) Clarence Ray, Kokomo, Ind., has submitted to us an elaborate set of drawings and description about a commutatorless d.c. generator, and he wants to know what demand there would be for a machine of this kind, and, if possible, its value financially. The dynamo in question works without commutator, as its name implies, and is supposed to have a much larger efficiency than other generators of the same kind.

A. As stated before in these columns, this journal cannot give advice as to the financial value of an invention. We stated before that even if we were to put down a figure this would at best be but a crude guess, as it would be practically impossible to approach the true value within 90 per cent., no matter what the invention was.

As far as the dynamo is concerned as submitted by our correspondent, we must say that we have been very favorably impressed with the idea. We have never seen anything like it, and from a careful study which we have made of the device we are quite convinced that it will work as stated by our correspondent. It is certainly the most ingenious invention which has been submitted to us so far, and should prove of great interest to manufacturers constructing generators. As far as we are aware of, there exists to-day no machine nor patent on a generator of this kind, and we would advise our correspondent to get in touch with a patent attorney at once and see what has been done in the art before. There is a chance that a similar idea might have been patented before, although we very much doubt it.

We have been so well impressed with this invention that we would like our correspondent to advise us what results he has had in connection with the device.

EDISON DEFINES GENIUS.

"Stuff! I tell you genius is hard work, stick-to-it-ive-ness and common se[illegible]e!"

In this short and trite sentence Thomas A. Edison, the wizard, sums up his successful career. But this versatile and brilliant inventor should have added genius is indefatigable in research, experiment and discovery and exhibits intense concentration of mind and love of learning.

Thomas A. Edison was born at Milan, O., in 1847, but when he was seven years of age his family moved to Port Huron, Mich., where he passed his boyhood. Edison spent but three months in the public schools, but received a thorough schooling at his mother's knee. Before he reached the age of twelve he had read Gibbon's "Rome," Hume's "History of England," Sears' "History of the World," and the "Dictionary of the Sciences."

PATENTS

IF YOU HAVE AN INVENTION which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention, and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of seventy years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand-Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to **Patents, Trade Marks, Foreign Patents,** etc.

All patents secured through us are described without cost to the patentee in the *Scientific American.*

BARON MÜNCHHAUSEN'S NEW SCIENTIFIC ADVENTURES.

(*Continued from page* 625.)

soned with a similar logic, and they had thus come to the conclusion that as Mars is so far removed from our sun the temperature on Mars must necessarily always be far below the freezing point. Accordingly they reasoned that life on Mars as we understand it was not possible. But then the telescope suddenly revealed that the Martian snowcaps *do* melt every spring, and if this is the case the temperature even in the arctic circles at times *must* be above the freezing point. But why?

"'The answer is simple enough. The earth has a very dense atmosphere with many clouds. On Mars the reverse is the case, where we have a thin atmosphere and practically no clouds all year around.

"'Professor Lowell estimates that over the earth as a whole the proportion of actual to possible sunshine for the entire year is 50 per cent. In other words, the sun only shines practically one-half of the time it might if there were no clouds. On Mars, on the other hand, the sun shines 99 per cent. of the time. There are no cooling rains or snows in the temperate zones either to cool the atmosphere, consequently a great deal more heat is absorbed and retained on Mars than is the case on earth. Further, an enormous amount of energy is lost on earth, where the sun rays must travel through a dense blanket of air, which is not the case on Mars, where the air is thin and clear. For this and other reasons too technical to dwell upon, we find that light and heat are practically the same on the two planets, with several points in favor of Mars.'

"While I was still turning these facts over in my mind, Flitternix suddenly pointed to the sky and shouted rather excitedly:

"'Look at the moons!' I followed his finger and I saw the wonderful spectacle of two full moons shining in the sky. It was still light and for that reason the effect was not as wonderful as we have since witnessed when we see Phobos and Deimos during the night time. At that particular time the moons shone rather pale as our own moon does in a bright afternoon with the sun still up.

"Phobos, the larger of the two moons, is but 4,000 miles distant from Mars and, as I mentioned before, it revolves around Mars in the incredible short time of 7½ hours. In a single Martian day it therefore revolves three times around Mars, consequently it rotates faster than Mars itself. Although it revolves in the same direction as Mars and the rest of the planets, namely, from west to east, on account of its greater speed *it appears as if it were moving from west to east.* Its speed to an unaccustomed human observer is really disquieting. While we were looking on we could actually see how terrifically fast Phobos moves. When Flitternix had first called my attention to it it was quite high up in the sky. Ten minutes later we watched it plunge with express speed below the eastern horizon! It is positively uncanny to see a heavenly body that looks as big as our moon perform such celestial gymnastics, but the fact remains. Deimos, the smaller of the two moons, revolves at a distance of 12,300 miles from Mars. But as it measures but 36 miles in diameter it naturally appears quite small as seen from Mars, even when full. At that afternoon when we saw it it did not appear very much brighter or bigger than the evening star as seen from the earth. As a matter of fact, it does not look like a moon at all

to Martians, as we understand that term; it looks rather like a very bright star. Even during the night its face does not always appear as a disc to the naked eye, even when it is full. It is too small and too far removed. Nevertheless it is a true moon.

"Having finished our contemplation of the sky, we turned anew to the view directly below us. Of all inspiring and majestic sights I do not think that there is one that can rival a Martian 'city.' I once thought that New York as seen from the Woolworth building was about the grandest view one could ask for, but it appears positively ridiculous compared with any of the Martian great centers.

"To begin with, the Martian cities are not built upon the ground for a very important reason. Nearly all of the Martian continents are deserts, irrigated only in comparatively small sections and near the great waterways. The land, therefore, which is absolutely flat without even small elevations, is sandy, as are all true deserts. For ages upon ages this desert sand has been rolling back and forward over the planet till it has lost the characteristics of real desert sand as you know it on earth. It has become a fine, impalpable dust, extremely choking if it finds its way into the lungs.

"This fine desert dust is the greatest bane of the Martians and they fight it constantly and heroically. But as nothing but vegetation—which, again, is dependent on water—will permanently stop the dust, the fight is almost hopeless, for the Martians lack water to irrigate the entire planet. Naturally the dust is not quite so bad near the waterways, but the large centers spreading for a few miles inland are not thus protected, especially if the wind blows from the land side over a broad expanse of desert. Even the slightest breeze brings its clouds of choking dust and a strong wind sometimes obscures the sky.

"But when it storms pity the poor Martians! Through the large telescopes on earth 40 million miles away astronomers have frequently seen huge sandstorms sweep over sections of Mars as large as France! Can you imagine what such a storm means? We witnessed one yesterday and it was awe-inspiring, terrific indeed. Hours ahead of the storm the Martians ran for their sheltered lofty houses and closed everything airtight. All traffic on the canals, on the ground, as well as in the air, ceased for two hours while the storm was in progress. From the eastern side of our host's windows we saw the approach of the dust. It came rolling on in gigantic red clouds like an ocean, and although it was in the forenoon the sun was blotted out almost entirely. The dust is so fine that you could hardly hear it as it was hurled against the thick window panes in immense quantities. On and on it came, seemingly without end; sometimes we would get a glimpse of sunlight, but oftener we were plunged in total darkness. After the storm had lasted for two hours it stopped as suddenly as it had appeared and the sun smiled down on us again as always.

"Within ten minutes after the storm myriads of aerial flyers could be seen spraying the buildings and structures with compressed air to clean out the red dust from the corners where it had accumulated. When we looked around this morning there was hardly any evidence of the terrific sandstorm of yesterday. Of course, such storms as the one we witnessed are rare and do not occur more than six times a year; nevertheless, all Martian houses and structures are built with a view of getting rid of the dust as quickly as possible when it does come in avalanches.

"Accordingly all buildings have sharp

YOU BE THE BOSS!

Become a master of men in this wonderful new profession. Get the big job—climb to the **top** in the great electrical industry. Electric Lighting Plants must have Meter Engineers. Nearly eight million electric meters now in use need **constant attention.** Half million more being installed yearly.

Earn $1200 To $3000 a Year

As Electrical Meter Engineer

The supply of trained men does not begin to meet the demand. The field is tremendous—growing greater and greater. Work is interesting, fascinating, profitable. The marvels of electricity interest and hold you captivated, as you study our simple, concise and complete course. Experience unnecessary. Just common school education. **Earn while you learn.**

Big Demand for Trained Men

We help you to a position when ready. Our graduates command respect everywhere. Only school teaching Meter Engineering. Get into this **new** profession—get the **high-salaried** job. YOU be the boss.

Big Money in Electricity

The electrical industries offer wonderful opportunities for boys with a liking for electricity. The salaries paid to trained men are large—promotion comes rapidly, and, best of all, the profession is not overcrowded.

The opening of new lines, from time to time, (such as wireless telegraphy and telephony), promise attractive and paying fields to those who wish to specialize. The *will to do* and *Special Training* will bring success to you.

The International Correspondence Schools of Scranton can help to make you an expert in electrical work. Hundreds of boys have already won success through I. C. S. help. You can do the same. Everything is made so clear that you can learn in your spare time, regardless of where you live or what you do. No books to buy.

There's big money in electricity. Get after it by marking and mailing the attached coupon today. Finding out costs you nothing.

gable or pyramid roofs, and every wall and balustrade is built with a gable. Every window sill points downward at an angle. There is not a structure on Mars that is exposed which is flat, or which has a single flat projection extending from it. Everything is built to get rid of the dust as quickly as possible, for this fine and extremely dry sand slides down a sharp incline with great rapidity.

"From the foregoing you will easily understand that the Martians cannot permanently dwell near the ground. It is an exceptionally calm day when your Martian can walk on his planet without his respirator hood over his head. From this it follows that as he cannot dwell upon the ground, and as intelligent beings as a rule do not care to burrow themselves into the ground, there is but one thing to do, and that is to go above the surface of the ground. Indeed, this is precisely what the Martians have been forced to do for thousands of years back.

"It was soon found that the ordinary dust did not usually rise higher than 400 feet above the surface of the planet. At this altitude the air is sandproof except for such severe storms as the one we witnessed yesterday.

"For this reason all buildings and structures on Mars, with few exceptions, are located 500 feet above the ground in order to make life bearable. Thus all 'cities' are built high up in the air, and it is this feature which gives the stranger his greatest surprise.

"Imagine immense metal towers stretching skyward mile upon mile, supporting a vast city raised 500 feet up in the air. Imagine these towers partly roofed over with metallic roadways and buildings and you have a faint idea of how a Martian 'city' appears.

"When we had first 'landed' on Mars we naturally thought that we had touched the ground. As a matter of fact, we had not 'landed' at all, but we were still 500 feet away from Mars proper. We simply had descended in the aerial Martian city, but this we did not know till later.

"Every building is constructed of the universal transparent material *Tos,* giving the structures a curious but pleasing appearance. The transparency of this wonderful material is so great that it is possible to actually look straight through an entire building, wherever there are no obstructions of opaque objects. I might say that the latter are rare, for the Martian loves nothing better than transparency and for that reason he builds nearly every object of *Tos;* from a table down to the floor, which, of course, is transparent, too. You might think that such a house, open to everybody's curiosity would bring with it many delicate as well as embarrassing situations, but this is not the case, at least not for the Martians. These people have long since learned that anything worth doing cannot possibly be open to criticism from fellow inhabitants; while closeted, non-transparent rooms make for nothing but laziness and vice. When all of your actions are open to the entire world you are more apt to lead an upright life than otherwise. For that reason no false, make-believe civilization exists on Mars as is the case on earth. For that reason, too, the Martian is an upright, healthy, truth-loving individual, not a hypocrite as are nine-tenths of the human race. The Martian has no secrets, he knows no vice, he has no scandals, and he has little occasion to feel ashamed of himself. Why? Because everyone can see at *all* times what he is doing.

"Pick up any one of your newspapers. What do their text pages contain? Seventy

Brilliant Light in a Jiffy

Everybody appreciates the value of Franco Flashlights. Around the home at night; motoring; out-of-doors; for boy scouts; mechanics; farmers and postmen, Franco Flashlights are indispensable. At a pressure of the finger they throw a brilliant stream of white light just where you want it.

Franco FRANCO **Flashlights**

are guaranteed absolutely to give you worthwhile service and satisfaction. The Radio Battery inside is the finest flashlight battery produced, will give more light and last longer. *At the Panama Pacific Exposition Franco Flashlights were awarded highest honors—Gold Medal and Blue Ribbon.*

Flashlight illustrated is 5½ inches long, fibre covered, nickel trimmings and will throw light a long distance. Patented "Wireless" feature prevents short-circuiting when in contact with metal. Complete with Radio Battery and Tungsten Lamp, at $1.00; everywhere.

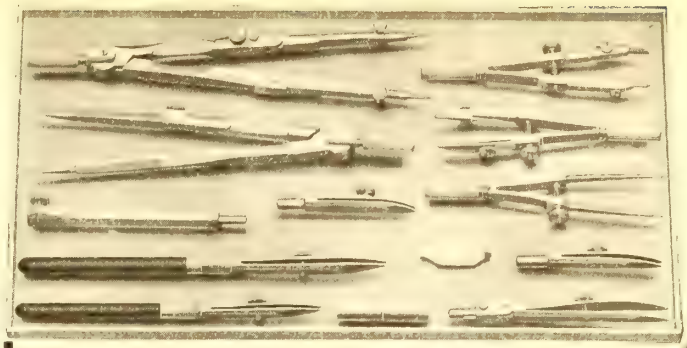
per cent. scandals, murders, war, law suits, gossip; 10 per cent. sports; 10 per cent. business; 5 per cent. science and advancement, and 5 per cent. miscellaneous subjects. If you place your whole humanity in transparent houses the scandals, murders, war, most of the law suits and the gossip will disappear automatically. Think it over!

"The great Martian 'cities' are laid out in semi-circles, or else rectangles, always one side quite close to a waterway. Moreover the 'cities' are not detached, but they are continuous; by that I mean that they run unendingly along the whole length of nearly every waterway. Thus on both sides of the waterways you will find the metal towers bearing on their top the Martian buildings. The so-called 'running cities' are only about one mile wide, running parallel with the 'canals.' Every 50 or 100 miles we find a large center which spreads out in form of a semi-circle or a huge rectangle, some of these large 'cities' recede from five to seven miles from the waterways. Of course, these large 'cities' are connected on both ends with the 'running cities'; for that reason there is no beginning and no end to the Martian 'towns.' Nor do they go by any particular name. Each spreading city has a number while the running ones, located between the spreading ones, have a figure and a symbol like our letters. Thus the Martian Capital at which we reside at present is termed 1. The first large 'city' toward the south is termed 2. The 'running city' which connects city 1 and 2 is termed 1A. Of course, the Martian symbol is not 'A,' this is merely my equivalent or my own translation for it. The numbers of the houses for quick orientation are termed in 'fractions,' according to their location. Thus, for instance, a house located in the 'running city' 1A is numbered $\frac{1A}{10}$. This means that it is the tenth house south, counting from the 'city' 1. As every Martian knows the location of every 'town,' the numbering system is both simple and does not lend itself to confusion.

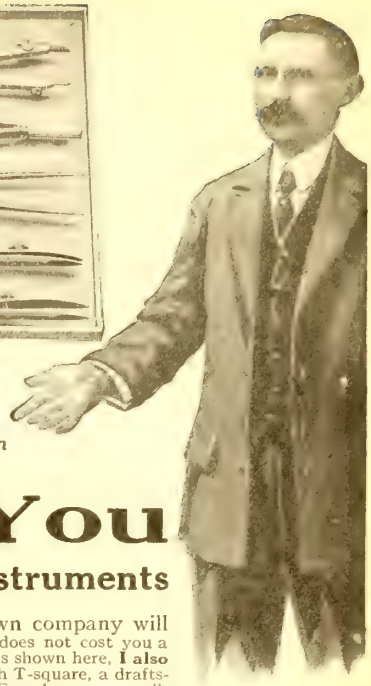
"As nearly all of the land on Mars is practically desert, except that near the waterways, it follows that no 'town' ever reaches more than 10 miles inland. This fully explains the vast 'connecting cities.'

"All the streets run perfectly straight and cross at right angles, American fashion. All buildings and houses are detached from each other, none are ever found built close together. Usually eight buildings constitute a 'block,' three to each side, with the center space left open.

"The 'blocks' are separated by wide arched roadways; wherever two of them cross each other, there are usually two bridges flung diagonally across which meet in the center.



"The roadways themselves are of a heavy metallic construction and are entirely perforated with round conical holes about one inch in diameter with about one inch of metal between them. By this method all dust and dirt falls through the streets to the ground 500 feet below. Thus the roads appear clean perpetually, even after a sandstorm. The houses.....but, hello, my chronometer tells me that I have but ten seconds left to talk before the telegraphone wire on my radiotomatic on the moon will be full to capacity. Well, good night, my boy, till to-morrow, good night!....."



* * * * *

The usual rap, r-r-r-ap, f-flum, f-flumm and everything was quiet once more.

This serial started in the May, 1915, issue. Back numbers are supplied at 10 cents each.

(To be continued.)

Because

I want ambitious men to become high salaried Draftsmen through my practical working training—therefore:

I Will Give You

This Set of Drawing Instruments

The Chief Draftsman of a large and well-known company will give you this complete draftsman's outfit absolutely free. It does not cost you a penny. Besides these Imported regular draftsman's instruments shown here, **I also give you absolutely free** a 20x25 inch drawing board, a 24-inch T-square, a draftsman's triangle rule, supply of drawing paper, 2 triangles and French curve, pencils and erasers, drawing thumb tacks, etc., in fact a complete and first-class **regular Draftsman's Working Outfit as soon as you enroll.** This is just the same kind of an outfit I use myself. Genuine working instruments. You could not get this outfit for less than $15. But now on this special offer, I will give it to you absolutely free.

And Train You for a $200 Position

I am Chief Draftsman of an old and well-known company. There is a constant demand for trained draftsmen all over the country and **I will give you just the kind of training that will qualify you to hold one of these big paying positions.** $125 to $200 a month straight salary is an ordinary pay for a good draftsman. I will give you just the kind of training that you need to hold one of these fine jobs, right in your own home during your spare time. **Start earning money as soon as you are my personal student.** I know the kind of training that you must have in order to get the highest salary—and that is just exactly the kind of training that I will give to you. During the last twenty years I have trained some of the highest paid men. Their success in the profession is well known. You can do as well—or better than they.

SPECIAL! For a limited time I am making a special price offer in order to complete a new class ready to start. Send for free book at once, to-day.

Send Me the Coupon For FREE New Book

Put your name and address in the coupon or on a letter or postcard now and send to me at once for my new book "Successful Draftsmanship." Find out about the golden opportunities that await you in our profession. Find out how you can get just exactly the kind of training that you need to hold a position paying from $125 to $200 a month at once. Absolutely no obligations in getting the book. Just put your name and address on the coupon. But send it now—immediately while I am making this special offer.

Here's YOUR Chance to Learn
DRAFTING
This Complete $15 Drawing Outfit and Full Instructions in Mechanical Drawing FREE

There's a good job waiting for you. The country is facing greater prosperity than it has ever before experienced. Far-seeing men are getting ready for boom times. Get this training now and share in the coming prosperity. We make the way plain.

CHARLES W. MOREY
President of the College and Head of a Large Chicago Firm of Civil, Mechanical and Electrical Engineers and Contractors.

Men Wanted
AT BIG SALARIES

This is a rare chance for a few wide-awake young men.

On account of the rapidly increasing demand for trained draftsmen Pres. Morey has issued orders that instructions be furnished to a limited number of young men who are inclined along engineering or architectural lines. Read about this great offer below—then mark and mail the coupon.

STUDY AT HOME Devote your spare hours for a short time only and learn this profitable and pleasant profession, and get in the class drawing the big pay envelope. Hundreds of men are in daily attendance at this old established college. In your own home you can do the same work these men are doing, and the same experts that teach them will guide you toward the big job. These well-known engineers prepare your instruction matter. Your work is examined and approved by them. They know exactly the practical training you need and they train you. No books to sell. Live, up-to-date blue prints of work in actual construction. In your own home you work with plans of machinery, buildings, steel works, etc., actually being constructed in Chicago, New York and other large cities.

Electrical Drafting and Design

No other similar correspondence course in America has a resident college of National reputation back of it, nor a faculty of active experts actually engaged in municipal and corporation engineering work. These men know exactly the kind of training you need because they are in constant charge of big work.

$45 COURSE FREE
IN MECHANICAL DRAWING

This College has set aside a limited number of Free Scholarships and will give the regular $45 Course in Mechanical Drawing Free with any one of the Home Study Courses named in the coupon below—this is in addition to the complete $15 Drawing Outfit which is also furnished to students free. Take advantage of this unusually liberal offer today, as it will be withdrawn when the allotted number of Free Scholarships has been awarded. It costs you nothing to get full information. No obligation on you.

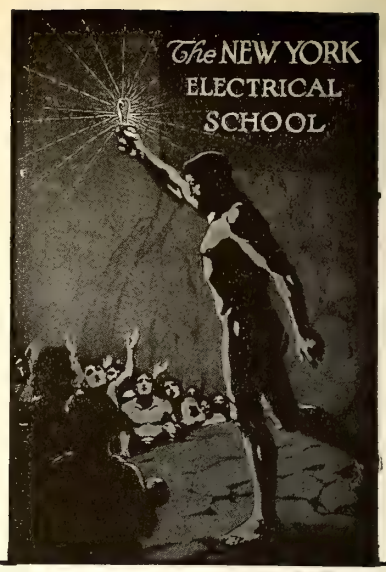
THE UTILIZATION OF THE SUN'S ENERGY.

(*Continued from page* 606.)

a partial rotation to the ratchet wheel w. As the current ceases the armature is retracted by the spring b, without, however, moving the wheel w. With the stoppage of the current the plates t t cease to be attracted and separate, thus restoring the circuit to its original condition.

Coming now to later developments of a practical nature in the line of solar engines and boilers, we may take up the work of Mr. Shuman, of Philadelphia, Pa., who later collaborated with a Mr. Boys, of England. They were able in their final developments to operate a 100 horsepower engine by means of solar energy. This plant was built at Meadi on the Nile, Egypt, and is shown in the large illustration here reproduced at Fig. 3. Prior to this excellent work, however, we may consider briefly the early solar engines developed and tried out at Philadelphia, Pa., by Frank Shuman, upon which work he started in 1906.



A year later he had running at Tacony, Pa., a practical plant of this type, which developed about 3½ horsepower by using 1,200 square feet of sunshine that was allowed to fall on a fixed, horizontal water box. This box was fitted with a glass top and a series of parallel horizontal black pipes were immersed in the water. These pipes, containing ether, exposed 900 square feet of surface to the solar radiation. The water also became heated and carried the heat to the underside of the pipes, thus realizing a greater efficiency. The ether boiled and its "steam" drove a small vertical, single cylinder engine. The exhaust ether vapor passed into an air surface condenser and the liquid ether from this was pumped back into the tubes of the sun boiler. It was found that this plant worked well even with snow on the ground, which is explainable from the fact that the permeability of the atmosphere is about 20 per cent. greater in winter than in summer.

Further tests and refinements to the Tacony plant by Mr. Shuman resulted in 1911 in an engine and boiler which showed considerable strides forward in their design, the ratio of 245 square feet of sunshine per one brake horsepower having been attained.

It may be mentioned here that the pipes constituting the sun boilers have invariably been *blackened*. For low temperatures lampblack has been used as the absorber, but where high temperatures were required platinum black was used.

The illustration Fig. 3 is that of the solar energy plant built at Meadi on the Nile, Egypt, by Messrs. Shuman and Boys in conjunction with several English scientists, including Mr. A. S. E. Ackerman, B.Sc. This plant made use of a 100 horsepower Shuman engine coupled with suitable auxiliary apparatus, as before mentioned. Five absorbers of the reflection type were utilized, as the illustration portrays. Each one measured 15 feet wide by 205 feet long. These were placed north and south geographically speaking, and were automatically heeled over, by being placed on suitable wheels, from an easterly aspect in the morning to a westerly one in the evening, so as to actually follow the sun. This caused an approximately even absorption of the solar rays all day.

The total area of sunshine so collected at this plant was 13,269 square feet. Cast iron boilers of suitable design were placed at the focus point of the reflectors, as shown in the illustration. They were covered with a single layer of glass which

THE N. Y. ELECTRICAL SCHOOL is the pioneer and premier school of the "Learn by Doing" method. When you have completed this Course you shall be fully qualified to handle ALL branches of Electrical industry.

The equipment of this School is unequalled and up-to-the-minute. No preparation needed to become a "learner" in this school. You can start to learn on any day of any week throughout the whole year. Send for catalogue.

DEPARTMENT OF SIGNALING
1810 Wilson Ave. Room 3383, Ravenswood Station, Chicago

enclosed an air space around the boilers proper. The concentration value of this arrangement was 4½ to 1. The maximum pounds of steam generated was 12 pounds per 100 square feet of sunshine, or the equivalent, to 183 square feet per brake horsepower. The best hours' run developed, at atmospheric pressure, 1,442 pounds of steam. Hence (allowing 22 pounds steam per brake horsepower) the maximum output for an hour was 55.5 horsepower (about ten times better than any previous results). This means 63 brake horsepower per acre of land occupied by the plant. Moreover, no marked reduction in the horsepower produced was noticeable in the early hours of the morning or in the late hours of the afternoon.

The engineers of the concern which made these tests at Meadi recommended that such solar plants were feasible and practical and that undoubtedly they would be a very good thing in such arid regions for irrigation purposes. One argument brought against them, however, was that the power would not be available in cloudy weather, but then the irrigation would not be necessary, was the reply.

Thus the fight goes on between Dame Nature and the scientists. Whether we shall ever have an efficient solar boiler and engine is a problem worth thinking about and a very interesting one at that, as we possess no greater source of natural energy, to be had without taxation or special leases from some money-grabbing coal, oil or other baron, than that of the sun. Some day we may be able to derive all necessary light and power, for our homes at least, by means of a solar-electric plant located on the roof, and who shall say that we must be taxed for utilizing such energy?

THE TESLA HIGH FREQUENCY OSCILLATOR.

(*Continued from page* 615.)

thousands of horsepower? However, this figures out better than might be expected offhand. With an input of 300 kilowatts at the Tesla coil primary exciting such a structure and considering that this amount of energy is discharged through the earth in six-thousandths (.006) of a second, then the rate of liberation of the energy will be 120,000 horsepower.

Many perhaps would doubt that even with their small experimental high frequency sets, where a high frequency ammeter placed in the high frequency circuit may register but *1 ampere effective current*, yet an average maximum surge for the oscillation passing through the circuit may and often does reach the value of *over 116 amperes*. As the amplitudes of each succeeding high frequency alternation is less than the one preceding it, of course the first oscillations are much higher than the average amplitude just mentioned, and consequently the peak value of the current which flows through the electrode and into a person (who may happen to be connected in series with a 110-volt, 32 candlepower lamp for demonstration purposes) may reach a very much higher figure than 116 amperes.

A tiny electric lamp on the front porch and another on the back porch, left burning all night, will keep night prowlers and burglars away, because no thief cares to take a chance in the light. They need darkness and black shadows for their protection. One two-candlepower lamp for the front porch and another on the rear porch can be turned on all night for a few cents a month, which is certainly cheap burglar insurance.

HERE is your future charted for you, based on the actual average earnings of trained and untrained men.

Which way will you go? You'll either go *up*, through *training*, to a position that means good money and more comforts as the years go by, or you'll go *down*, through *lack* of training, into the ranks of the poorly paid.

It rests entirely with you which way you go. You can make or break your own future. And *now* is the time to decide. Not next year, not next month, but *now*. You *can* go up if you want to. You can *get* the training that will command a trained man's salary. The International Correspondence Schools have helped hundreds of thousands of men to qualify for advancement. Let them show *you* how *you* can prepare yourself, in your own home, for the position you want in the work you like best.

At least, *find out* what the I. C. S. can do for you, by marking and mailing this coupon. It will be the first step upward. Choose your future from this list, then get this coupon into the mail today.

HOW TO ORGANIZE AND CONDUCT A RADIO CLUB.

(*Continued from page 627.*)

ing and receiving sets constructed entirely by members of the club. The crowds of visitors evinced great interest in this particular feature of the exhibit.

The Atlanta Radio Club has an active membership of 25, each member possessing a complete sending and receiving station. A meeting is held every two weeks, at which many subjects of interest are discussed. The members converse every night with each other, the length of conversation, form of calling, signing, etc., all being done in strict conformance to certain by-laws of the club's constitution.

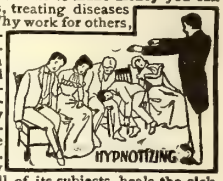
The club has a *special operator,* who sends out official notices to all members on a certain day and hour, and also has an *inspector of stations,* whose duty is to adjust each station so that it will cause a minimum of interference, and also to see that each station conforms to the Government radio regulations regarding wave length, power, etc.

A Club Laboratory.

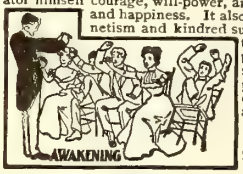
Many amateur radio organizations have arranged in one way or another to fit up shop facilities for the use of the members. Special appropriations, obtained by outside contributions or by levying an assessment on the members of the club, have served to offset the cost of the machinery necessary. A small lathe is probably one of the most useful articles which a club should purchase for such a laboratory. This may be followed by a small drill press, another necessary accessory which the individual members would probably not have the good fortune to have the use of in their own homes or laboratories. Aside from such machinery necessary in winding coils, making up special apparatus parts, etc., there is a very urgent need for a good *wave meter,* and also, when possible, a *decremeter.* From the various magazine articles, particularly in *The Electrical Experimenter* for November, 1915, it is possible to build a fairly accurate wave meter without a special calibration against a standard wave meter. Any wave meter can be calibrated at a nominal expense by the Bureau of Standards, Washington, D. C. The secretary of the club should write to the bureau, obtaining in reply information as to the cost for calibrating the particular instrument in hand. Likewise, it is possible to have a decremeter calibrated. If access is had to any local school or college having such standard instrument on hand, it is possible that arrangements can be made with the instructor in charge to compare and check up the club's instrument with same.

[*Be sure to read the conclusion of this important article in the April issue. It takes up such timely subjects as the "Rules for Conducting a Meeting," "Order of Debate," "Formation of Club Library," "List of Most Desirable Books," etc.*—EDITOR.]

THE CHORALCELO, A WONDERFUL ELECTRIC PIANO.



(*Continued from page 607.*)



necessary to place within them a small piece of iron, so that the electro-magnets may attract them. Instruments which are operated by this method are depicted in Fig. 3. The one toward the right is an instrument which imitates a flute. The electro-magnets are placed underneath the tubes, which are made out of wood and act as resonant chambers. The magnets are caused to act on iron discs mounted at the lower end of the tube. Another style of flute instrument is illustrated in Fig. 4. This employs a different variety of tubes, ranging from a very high tone to a very

HYPNOTISM!

Be a HYPNOTIST and MAKE FUN and MONEY!

It takes but a few hours to learn. The study is both easy and fascinating. Hypnotism is an endless source of fun and wonder. If you know how to Hypnotize you can perform some of the most marvelous feats imaginable. You can do a hundred amazing things that other people cannot do. You can surprise your friends and make yourself popular. You can place others under this strange and mystic spell. You can compel them to think, act and feel just as you wish. If you want to **make money** you can do so by giving entertainments, treating diseases or teaching the art to others. Why work for others, when you may master this money-making profession so easily? Investigate **NOW!** You may learn at your own home. I will send you my **free treatise** for the asking. It tells you about Hypnotism and how you may easily learn it. It is profusely illustrated and is written in a simple style easily understood by all. Anybody may learn from it of how the Hypnotic Spell sways the will of its subjects, heals the sick, reforms the degraded, overcomes bashfulness, helps to trade or position, amuses an audience for profit, and gains for the operator himself courage, will-power, and a means to health, wealth and happiness. It also treats fully on Personal Magnetism and kindred subjects. Remember, this treatise is **absolutely free.** Simply write for it, and it will be sent by next mail, all charges paid. Don't send any money or stamp, but send your name and address **today.** Address:

NATIONAL RADIO SCHOOL, 1405 U St. Washington, D. C.

low one. The smaller pipes emit the latter tone, while the larger ones produce the former.

The instrument shown in the center of Fig. 3 illustrates a brass chime. The tones are produced by hammers, each of the tubes being supplied with one. These are operated by electro-magnets, as perceived in the upper bracket of the stand. These are also connected to the same keyboard.

The very deep tones of an organ are produced by vibrating diaphragms placed beneath metal horns. A pair of electro-magnets are held a minute distance away from the diaphragm and serve to vibrate the latter when the pulsating current is applied. The volume of the tones are powerful and are very pleasant, although they are very low. By increasing the power in the electro-magnets the strength of the tones are so much increased that it is almost impossible to imagine the effect.

"Echo" combinations also may be installed without limit wherever their effect may be most beautiful at any distance from the master instrument. Thus the greatest cathedral may be filled with a glory of sound. The tower may be used to flood the surrounding country with the same divine melody. It may also be carried to the quiet cloister and to the private room. An instrument played in one place may repeat its music elsewhere.

The Choralcelo was developed and its wonderful basic principle discovered by Melvin L. Severy, of Arlington, Mass., and George B. Sinclair. These savants have been working for twelve years to bring this musical instrument up to the perfection which it has reached to-day. One cannot predict its possibilities or limits, as it is really still in its early stages of development.

We are indebted to Wilber E. Farrington, of the Choralcelo Co., for our illustrations.

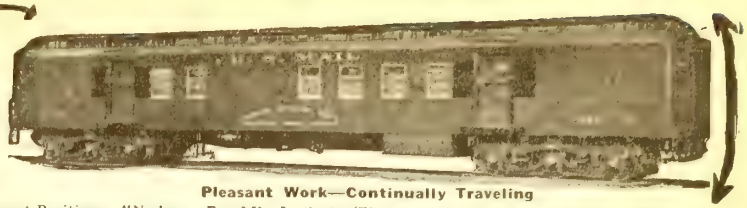
a heat wave, that it had a density of about $\frac{2}{3} \times 10^{-20}$ pounds per cu. ft., which would make a volume of ether the size of the earth weigh only a small fraction of a pound.

Whether the ether is continuous or discontinuous, at least it is not matter in the ordinary sense, and it certainly is not atomic; that is, divisible into particles akin to atoms. There are no gaps as would exist between such particles, and the shortest light waves are carried by it as well as the longest. Likewise we now see that it is the universal medium of action for several different and wonderful forces.



To gain a mental picture of this medium let us consider a hollow sphere H, H^1, as in

Extraordinary Prices on These Oliver Typewriters

Here's Your Chance!

Accept It

No. 5 OLIVER

Must Sell a Thousand Machines Quick

The great European War makes it impossible to ship typewriters to Europe. We have 1,000 No. 5 Oliver machines which we must sell quick. And we are determined to dispose of them in this country at prices which defy competition. These grand typewriters must be sold at once. Here is a great opportunity to secure an Oliver at bed-rock prices. You will never have another chance like this, as the small number of Olivers at this ridiculously low price will be sold to the first thousand readers sending in the coupon. Are you going to be one of these fortunate people? Act now if you want a good typewriter. Investigate today.

Genuine Oliver Typewriter
Guaranteed a Lifetime

These machines come to us fresh from the factory. Money will not buy greater typewriter value. They have all the wonderful Oliver advantages—visible writing, U-shaped type bar, built-in tabulator, marginal release, universal keyboard with six extra characters, etc., etc. Each full standard size, complete with every accessory and full instructions for operating.

The Oliver has the lightest touch and greatest durability of any typewriter made. Anyone can operate the Oliver successfully.

We will sell you one on the easiest terms ever known. Better still, we cover every single machine with a lifetime guarantee. Other machines are guaranteed for one year. But we have such confidence in the No. 5 Oliver that we will guarantee it for life. When you buy an Oliver you buy "for keeps."

Half the Price of Other Machines
Payments Just Like Rent

These 1,000 machines must go at once. And the price we make is so low that we do not dare even publish it. We can quote this price only in a confidential letter. Ask for it, if you need a machine. Don't wait until they are all gone before investigating. Mail the coupon or a post card today. Our price and terms will surely astonish you.

And remember that this is a regular $100 machine, with many thousands in use all over the world right now. We can always undersell manufacturers, because we have no salesmen with their big salaries and expenses. All of our machines go direct to the consumer, and he gets the saving.

And right now we are going to cut our own low price clear to the bone. Seize this opportunity while you may, for we doubt if it ever can be repeated. At the astonishingly low price we are quoting, these thousand Oliver Typewriters will all be disposed of in a very short time.

Get Our Amazing Price and FREE Trial Offer!

Send for our offer today. Use the coupon or a post card. Find out all about our sensational cut in prices. A few cents a day will buy your Oliver. And we will let you try one free, without sending us a single cent. Mail the coupon now, whether you're ready to buy or not. Then you will know whether you can afford to do without a standard No. 5 Oliver any longer.

Thousands of dollars were gladly spent

to compile this book

NOW OFFERED

to you for the unusual price of

35c.

Postage on 1 lb. extra

CONTENTS

Tells you quickly and accurately either call letter or station name and location of **any** and **every wireless station in the entire World.** Obviates that irritating moment when you hear an unknown call and have no means of quickly knowing who it is. Makes it worth while sitting up late at night to hear that faint and far off foreign call, for with it, at least, you can tell whom you hear. **Contains 222 pages of information worth its weight in gold,** lists over 15,000 ship and shore stations by **BOTH** nationality, location and call letter being cross indexed to give location, ownership and station designation.

A REALLY REMARKABLE OFFER

Imagine a finely cloth bound book 5½ x 8½ inches and ⅞ inch thick in size, **our illustration is full size,** containing 222 pages of information obtainable nowhere else and printed on an excellent grade of book paper and from type unusual for clearness and ease of reading. Not only is it up to date, but provides means for the insertion in their proper places of new calls of **every nationality** whenever assigned. Positively the best work of its kind ever offered and **WORTH $2.00 PER COPY.**

HOW IT IS POSSIBLE

This remarkable offer is possible only because of the financial difficulties which prevented the publishers from marketing a book which cost them thousands of dollars to compile alone, while thousands more were spent in editing, composition, printing and binding. Being exhausted the printers came to us as the logical outlet and we offer you these books at a price less than they actually cost to produce.

AUTHORS

The book was compiled by **FRANK A. HART, Chief Inspector of The Marconi Wireless Telegraph Co. of America,** and **H. M. SHORT, resident Inspector (U. S. A.), Marconi International Marine Communication Co., Ltd.** Need we say more as to the authority which these men have at their command to compile so noteworthy and necessary a book?

DELIVERY

We have on hand a very limited number only of these books and **NO REPRINTS WILL BE MADE.** We cannot, therefore, urge too strongly that you send in your order at once. All orders will be filled in the order of their receipt. Better **send for it TO-DAY** and make sure of getting the greatest book value possible to get. When you get the book you will say we've underestimated the value we offer.

NOTE! POSTAGE IS EXTRA ON A SHIPPING WEIGHT OF ONE POUND.
So include sufficient postage with your remittance which should be in cash or by money order.

EXPERIMENTER PUBLISHING COMPANY, Inc., BOOK DEPARTMENT, 233 Fulton Street, New York, N. Y.

MARVELS OF MODERN PHYSICS.

(*Continued from page 665.*)

Fig. 3, consisting of two hemispheres connected by a coiled spring on the inside. Now we may consider these hemispheres as uncharged or rather the positive and negative charges exactly balancing each other when they are together. If now the hemispheres are electrically charged in a suitable manner, we may consider the positive as separated from the negative, and the two hemispheres as stretched apart. There is a strain in the ether between these two charges that is analogous here to the tension of the stretched spring.

Take a charged Leyden jar for example. Here we have two opposite charges bound to each other by the strain existing in the intervening medium. The mechanical illustration of this in Fig. 4 is almost self-explanatory. A rope attached to two springs passes over two pulleys. The weighted ends of the rope are the coatings of the Leyden jar, and an excess of weights on one side or the other constitutes the charge. Here the strain between the coatings is shown by the springs again, and if the weights are suddenly evened up, the oscillatory nature of the spark discharge would be aptly illustrated, for the springs would vibrate back and forth "charging" and "discharging" the coatings till equilibrium was reached. Now it is very much a question of whether electricity is a function of the ether or vice versa; that is, whether the electric charge causes the ether-strain or whether the ether-strain causes the charge. One is certainly the accompaniment of the other apparently.

The fact is evident, however, that the ether is a medium for the exertion of forces, either electric or magnetic, and it seems that gravitation is still a third form of ether-strain. Little direct connection is seen yet between it and the other two, but then it must be remembered we know but little of the exact nature of any one of them or even of the "ether." We must content ourselves to live and learn, even though the learning at times seems slow.

[This is the second of a series of papers specially prepared for *The Electrical Experimenter* by Mr. Rusk. Part I appeared in the February issue.—EDITOR.]

A NOVEL RADIO INDUCTIVE TUNER.

(*Continued from page 628.*)

extremely sharp tuning without the use of variable condensers, and no dead-end effects will be experienced. This instrument is the invention of Charles Horton, a well-known experimenter in the field of radio telegraphy.

Learn Electricity

Earn $2500 to $4000 a Year

Your CHANCE has come! Your chance for **big money.** Your chance to do the kind of work you'll be proud of. Your chance to go into business for yourself. Think of it! You can now qualify AT HOME for that most wonderful of all fields open to the ambitious man—the great field of ELECTRICITY! Yes, no matter who you are, where you live or what you do, I will take you in hand and make you an EXPERT ELECTRICIAN so that you should easily earn $2,500 to $4,000 a year and more. And I'll do it so quickly and with so little effort on your part that you'll wonder how it was possible.

LEARN AT HOME

What if you don't know a thing about electricity! What if you've never had a bit of electrical experience. All I ask is that you give me a little of your spare time. I will instruct you personally and make the whole matter so simple for you that you can't help but learn. You don't have to buy a lot of books or equipment. You can master MY personal instructions easily right at home. **I've solved** this question of teaching electricity. I'll show you **I have** by giving you 20 personal lessons ABSOLUTELY FREE. Almost from the **very first** instructions you will have the knowledge and skill to do practical, electrical work—work that you can demand good money for doing. You can **earn as you learn—more** than pay for your instruction as you go along.

Be An Electrician

Think! When you have finished my instructions you are an EXPERT ELECTRICIAN! **You are right then and there ready to take a** big paying job or start in for yourself. I will train you until you consider yourself competent regardless of the time it takes. I not only show you how to do expert electrical work but show you how to estimate on jobs so you can take contracts at big profits. That's what it means to be personally trained by a man of **my practical experience** in every phase of electricity. Decide today to take advantage of my big free 20 personal lessons offer. Don't let the question of money bother you. I make the cost so small and the payments so easy that you won't miss the money.

MEN WANTED Wherever you go there's always urgent demand for Expert Electricians and at big pay. That's because the watchword of the age is, "DO IT ELECTRICALLY." Electricity advances so fast that there's a big shortage of competent electricians. And the demand is constantly increasing every day.

20 Complete Lessons FREE!

That's the sensational offer I am making now to a few more ambitious men. I make it for two reasons. 1st. To show you how easy my personal instructions are to master. 2nd. To secure quick action on the part of a few more prospective students. This offer means that you get 20 complete personal lessons ABSOLUTELY FREE! But you must act quick. The offer closes in 23 days. Send coupon or postcard at once. I'll send full particulars immediately. Mail coupon **today—sure!**

Books You Must Have

100 PAGES, 88 ILLUSTRATIONS

TWO REMARKABLE BOOKS

How to Make Wireless Sending Apparatus

THIS book will surely be welcomed by every wireless enthusiast and by everyone who is fond of making his own apparatus.

This book contains more information on how-to-make up-to-date sending apparatus than any other book we know of. Thirty different pieces of apparatus can be made with materials that most anyone can obtain without much trouble; the illustrations and descriptions being so clear and simple that no trouble will be experienced in making the instruments. Only strictly modern and up-to-date apparatus are described in this book and if we asked you 50 cents for it we are sure that you would consider it a bargain.

This book has been written by twenty radio experts who know how to make wireless sending apparatus and for that reason you will gain by their experience as well as by their experiments.

The size of the book is 7x5 inches substantially bound in paper; the cover being printed in two colors. Contains 100 pages and 88 illustrations. There are quite a few full page illustrations giving all dimensions, working diagrams as well as many photographs showing the finished apparatus.

PRICE 25c. PREPAID

How to Make Wireless Receiving Apparatus

WE know that this book will surely be a boon to every "How-to-make-it" fiend. It has been written and published entirely for the wireless enthusiast who makes his own receiving apparatus; the twenty radio constructors who have written the articles are well-seasoned in the art and know whereof they speak. You consequently profit by their experience.

Only strictly up-to-date and modern apparatus are described and only those that the average experimenter can make himself with material that can be readily obtained.

We believe that *this book contains more information on how to make wireless receiving apparatus than any other book in print* and you will find that it is easily worth double the price we are asking for it.

The size of the book is 7x5 inches, handsomely bound in paper; the cover being printed in two colors. Contains 100 pages and 90 illustrations. There are a number of full page illustrations giving all dimensions, as well as photographs showing finished apparatus.

PRICE 25c. PREPAID

100 PAGES, 90 ILLUSTRATIONS

THE EXPERIMENTER PUBLISHING CO., Inc.

Book Dept. 233 Fulton Street, New York

KILLING THE SMOKE NUISANCE ELECTRICALLY.

(*Continued from page 610.*)

lately in precipitating acid mists, such as are generated in acid producing plants. Figs. 7 and 8 illustrate an experimental outfit for such a purpose. The large circular drum carries a helix of wire which serves the purpose of a ground, while another terminal is placed inside the drum, in the usual way. The connections from the high tension transformer are made to the helical coil and the interior conductor respectively. The pan on which the precipitator is placed is used for collecting the condensed mist which is being generated by the acid making apparata. Fig. 7 shows the precipitator when the current is off, while Fig. 8 depicts same when the current is on. Note the difference between these illustrations.

When will these wonders cease? Electricity cleans our floors, washes our dishes, and now by its power we can filter out the fine solids from smoke without creating a back draft or in the least affecting the operation of the furnaces.

It may be thought that when these smoke precipitators are installed it will cause the firemen to get careless, as a smoking stack is evidence of a badly tended fire, but such is not the case, due no doubt to the inbred pride that all mechanics take in doing their work properly

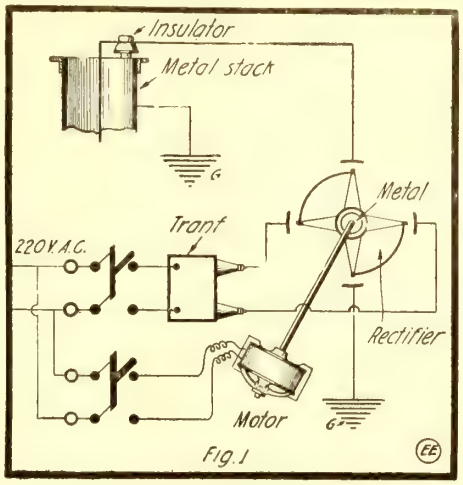

Fig. 1. Diagram of Electrical Smoke Precipitation.

Besides most up-to-date power plants are equipped with recording charts, which register the smoke produced, steam pressure gradient, etc., for every minute of the 24 hours.

IT'S INVALUABLE YET CAN'T BE BOUGHT

Just as you will receive it, cloth bound, size 7 x 10¼ ins., 160 pages, 20 lessons, 350 illus., 30 tables, with every bit of information on Wireless you can possibly want, besides valuable information on Electricity, Magnetism and Theory of them **—and it's FREE as explained.**

Will you take a 20 lesson Wireless Course absolutely FREE—even postage charge prepaid?

A course that tells you everything you can possibly want to know about "Wireless" starting off in Lesson No. 1 by explaining the Principles of Electricity. The Second and Third Lessons are devoted to magnetism, motors; generators and wiring. And then, by simple easy stages this wonderful Course takes you into "Wireless." The mysteries of "Wireless" are unfolded to you by the use of such simple language so skillfully used, that of necessity you must understand every word. The subject is not treated superficially, however, for there is a whole lesson devoted to the Theory and Mathematics of this epoch marking subject. To lend charm to the Course, the last Lesson (No. 20) is devoted to a history of Wireless and the men who developed it. The wireless course positively cannot be bought, but will be sent absolutely free with a full year's subscription (12 numbers) of the Electrical Experimenter at $1.00. It's the biggest dollar's worth you can ever buy anywhere at any time. Send for it to-day enclosing $1.00. Send **now** before you forget. The coupon below is a convenient way. **But do it now.**

VIA "SAYVILLE" TO BERLIN.

(Continued from page 630.)

go at night, as the sending conditions are then better. When Germany gets these messages she sends back the letter "R," repeated time after time. This means that she has received the message and understands.

Messages come in to Sayville written in all kinds of languages—English, German, Russian, French, Portuguese. These are translated into English and turned over to the censors, who examine them carefully for hidden meanings before they are put on the tape.

When the Government sends a message to Germany it goes by code. As soon as Secretary of State Lansing has affixed his signature the message is taken by the chief clerk of the State Department to the cipher rooms. The different pages are distributed among the cipher clerks, who begin turning the words into code. After the message has been deciphered it is turned over to another set of clerks, who check it carefully.

The secret code books of the State Department are guarded most carefully. Life is to be expended at any time to defend them. In fact, they are guarded as carefully as the code books of the navy, whose covers are so heavy that when thrown into the sea in case of emergency they will sink instantly.

LEARN the AUTO BUSINESS

Earn a Splendid Salary or Have a Business of Your Own

The Auto business is growing by leaps and bounds; there are better opportunities now than ever before, for properly trained men as Chauffeurs, Demonstrators, Mechanical Experts, etc. Over 3,000 of our graduates are making good money. **Most Up-to-Date—12 Years of Success.**

Latest equipment including 8 and 12 cyl. cars; latest types motors and lighting and starting systems.

Individual Instruction. Tuition and Board reasonable. Write at once.

CLEVELAND AUTOMOBILE SCHOOL
2343 Euclid Ave. CLEVELAND, O.

We Guarantee First Grade Commercial Operators' Licenses

The Largest, Best Equipped and ONLY Practical Radio School in New England

LEARN WIRELESS

Last year every one of our graduates successfully passed his required commercial Government Examination upon the first trial. Send a stamp for new fall prospectus. Winter classes now forming.

Scientific Exchange Columns

UNDOUBTEDLY you have at the present time some things for which you have no further use. Do you wish to exchange them for something, for which you have immediate use? There is no surer and quicker way to do this than by advertising your articles in these columns. The **Very** people, the **Only** people, who could possibly have a use for your things read this journal. More than 40,000 interested people will see your ad. It is furthermore the cheapest advertising medium for you in the country. Dealers' advertising accepted in Opportunity Exchange Columns only.

The rates are: Two cents per word (name and address to be counted) minimum space 3 lines. Count about 7 words to the line. **Remittance must accompany all orders.** No advertisement for less than 30c. accepted.

We reserve to ourselves the right to refuse any advertisement which we consider misleading or objectionable. Advertisements for the April issue should reach us not later than March 5th.

The Classified Columns of "The Electrical Experimenter" Bring Positive Results.

Subscribers experiencing trouble in dealing with any advertiser should notify the publisher very promptly.

FOR SALE — 1½-pint Leyden jar, ½-k.w. zinc spark gap, Leyden jar discharger, books on adventure; everything practically new. For list and prices, write to Robert S. Zimmers, 2822 Broad Ave., Altoona, Pa.

$4.50 TAKES parts of loose coupler advertised in February Popular Science Monthly, page 131, excepting mahogany front, instead of hard rubber. Urban McMiller, 3107 29th Ave., Minneapolis, Minn.

FOR SALE—Electro potentiometer, 95c.; electrolytic detector, 85c.; single slide tuner, $1.25; Mesco double slide, $2.50; mineral detector, $2.75. Vincent Natalish, Jr., 68 West 56th St., New York.

FOR SALE—Receiving outfit, receives 2,000 miles; will receive time from Arlington. Make offer. John Fouhy, 1428 Blue Hill Ave., Mattapan, Mass.

BIG SNAP—One Ives Electric train; practically new, 3 pieces, 8 straight track, 8 curved, value $5.75; want $3. H. Ananiantz, 700 W. Washington St., Los Angeles, Cal.

FOR SALE OR EXCHANGE—A 6-v. 6A dynamo motor that cost $12.80; three 2-volt, storage batteries, never used, $2 a piece, and 6 different-sized flashlights without batteries. Kenneth Jennings, Mattapan, Mass.

HAVE No. 2 camera; Stevens "Crackshot" rifle, $8; medical coil; want telegraphs, Kodak, photo album, wireless or boxing gloves. Elwell, 115 Cox Bldg., Rochester, N. Y.

FOR SALE—Electro Importing Co. instruments, used one week. Loading coil, lead peroxide detector, potentiometer, 50-ohm relay, half-inch spark coil, small spark gap. Write for bargain prices. C. Alleman, 1408 Madison St., La Crosse, Wis.

FOR SALE—BIG BARGAINS.

$7.50 Electro Loose Coupler	$5.00
$5.50 Electro Spark Coil (1½ in.)	$3.75
$4.50 Radioson Detector	$3.00
$4.00 Mesco, 150-ohm Relay (new)	$2.75
$2.50 Electro Sending Condenser (new)	$1.75
$2.50 Electro Loading Coil (new)	$1.75
$2.00 Omnigraph and 5 dials	$1.25

All the above are in perfect working order and condition. Sent within 24 hours of receipt of order. Address Fred Eckstein, River Road, Hoboken, N. J.

FOR SALE—One-inch Bulldog spark coil, $3; electrolytic interrupter, $1.25; electrolytic detector, 75c.; potentiometer, 50c. Will pay cash for audion. Robt. Sandifer, Eldorado, Kan.

FOR SALE—Sending outfit, consisting of a 2¼-in. coil, navy gap three, condensers, key, and storage battery of 8 volts, 80 amp. hours, for $18; or sold separately. Fred Carlotte, 78 Christopher St., New York, N. Y.

FOR SALE—Four-horsepower motorcycle engine in fine condition with carbureter and spark coil. Has connections for carbureter and oil, and is just the thing for cycle car or air wagon. Price $15. L. E. Beckley, Ukiah, Cal.

I HAVE for sale or exchange 2,000-ohm Brandes 'phone, qt. Leyden jar, $7.50 loose coupler, typewriter Rem. No. 6 in A1 condition, 2-cylinder gasoline engine, 14-horsepower, air cooled, in good running shape, 12-gauge Remington shot gun, pump action, hammerless, as good as new, numerous electrical and mechanical books. All the above is in practical, A1 condition. I will trade for anything electrical or mechanical, or sell very cheap. Don't hesitate to write me, for I have some bargains. I had rather sell the above articles. E. A. Hahn, McNary, Ky.

FOR SALE OR EXCHANGE—One complete sending and receiving wireless set with 2,000-ohm 'phones; will sell at a sacrifice. For full particulars write me. Would also like to buy or swap accessories for O Gauge Electric trains. George Adams, 601 North College, Charlotte, N. C.

MUST SELL—Circumstances force me to sell my ½-k.w. Packard; used two months; $8.50 brings it prepaid. L. A. Walker, 1716 South 20th St., St. Joseph, Mo.

HAVE Excelsior printing press with outfit, camera outfit, Roller organ, postcard projector, wireless apparatus. What have you? Nathaniel Leek, Amagansett, N. Y.

FOR SALE—Brandes Superior 'phones. One 'phone and head band new. Other 'phone in good condition, $3. Arnold's special make loose coupler, primary 12-in. long, fine instrument; can be used three different ways, $7; Murdock $3 variable, $1.50; large cabinet, good mahogany finish; has two tap switches and taps also test detector, $1.50; complete set for $10.65. Edwin Cohan, 601 West 156th St., New York.

FOR SALE—Two tuners, value $7.50; sell for $3.50, or $2 each; $5 Ferron detector, $2.50; $5 Murdock variable condenser, $3; $3 aerial switch, $1.50; $9 cash for whole outfit. All bought new and in good condition. Ellsworth Davis, Morrice, Mich.

WANTED—Second-hand dynamo cheap (110 v., about 10 amp.) or smaller machine; send description. Clarence L. Robinson (Curtis Rte.), Waynesville, Mo.

HAVE telegraph set, step-down transformer, 110 A. C. to 8 D. C., and drawing set; want 2,000-ohm head set. Write. Stephen Kent, 92 Campbell St., Pawtucket, R. I.

FOR SALE—No. 3 Brownie camera in excellent condition with portrait attachment for same; developing and printing outfit with instructions. All for $7. Write. Walter Curnutte, Rivesville, W. Va.

MOTOR WHEEL WANTED—Have up-to-date receiving outfit, complete in every way, including audion, Blitzen variable, Brandes 'phones, commercial loose coupler, etc., 1-k.w. quick-throw aerial switch and 600-volt lightning switch also included; want to exchange for Smith motor wheel in good condition. All inquiries will be answered. Edward J. French, Peekskill, N. Y.

HAVE $12 mail-order course, $5 stamp collection, $3 "Solid Receiver"; want good receiving set, or other wireless instruments. Mort Calcott, East Liverpool, O.

FOR EXCHANGE—Cameras 5x7 Century outfit, 3A Eastman Kodak, Premo Filmplate outfit, pair prism binocular field glasses, a $20 electric postcard projector, Savage automatic self-loading rifle, 22-cal.; two hammerless revolvers, tools, etc.; want electrical goods, open core transformer, or 1-k.w. closed core, a Tesla coil, or what have you? Odell, Optometrist, Fremont, Mich.

FOR SALE OR EXCHANGE—Experimental laboratory equipment consisting of volt meters, galvanometers, Wheatstone bridges, and other electrical instruments, together with large quantity of telephone relays, drops, jacks, transmitters, receivers, magnet wire, granular carbon, carbon electrodes, chemicals, small dynamo, lathe, drill press, filing cabinets and other equipment. State what you want. H. R. Van Deventer, Box 591, Sumter, S. C.

FOR SALE CHEAP—Complete amateur station, sending and receiving set, and large aerial; will sell for $15; worth twice as much. If interested, write. Ed. Guilmette, 343 Mason St., Woonsocket, R. I.

FOR SALE OR EXCHANGE—Complete volumes of Popular Electric magazines, Nos. 2, 3, 4, 5, 6; make reasonable offer; all ready for binding. William Kirsch, 782 Bergen St., Newark, N. J.

POWERFUL 11-in. water motor, $4.25; $15 Erector outfit with $3 motor, $8; 22 rifle, $1.75, cost $4.50; will exchange for audion bulb, 3,000-ohm 'phones, Multi-Audi-Fone and aerial. Archie King, North St., LeRoy, N. Y.

COMPLETE "Talking Head" for the construction of a telegraphone, will be exchanged for any of the following instruments: A hot wire ammeter, Weston or Keystone voltmeter, small dynamo, opera glasses, variable condenser, or what have you? Samuel Cohen, 1936 Pitkin Ave., Brooklyn, N. Y.

Opportunity Exchange

No. 1120.

THE AMCO NAVY TYPE RECEIVING TRANSFORMER

It represents the latest advance in design, the ideas have been perfected by our engineers. No guesswork about it. Can be set to receive any wave length. The illustration shows it as it is. The primary winding is enclosed in a cabinet, the sides and top of which are polished hard rubber. Two 15-point switches are mounted on the front. One switch controls the primary in groups of several turns and the other controls one turn at a time. The entire variation of the primary is thus secured by the rotary motion of two knurled knobs. The secondary may be varied from 1 to 225 turns in steps of one turn at a time. The windings are especially adapted to long wave lengths. The secondary is wound with green silk covered wire. The ends are HARD RUBBER, turned and polished. Secondary variation is secured by a 12-point switch which makes it possible to secure a very fine adjustment. PRICE, ONLY $15.00

Succeed Through Electricity

This interesting story shows you the way to greater success in the Electrical Field.

This is the Electrical age. Electricity now controls more trades, directs more men, offers more opportunities than any other power that man has yet discovered. Through *exact* knowledge of Electricity you will advance in salary and position.

Hawkins Electrical Guides Will Show You How

These books are the standard works on Electrical Science. They are a complete and up-to-date course in Electrical Engineering, presenting the information in a way you can use it. Only $1.00 per volume and owners of the set say there are no better electrical books published at **any** price.

Specially Arranged for Home Study and Reference They fit your pocket and your pocket book. Beautifully bound in **flexible** black leather with gold edges. Easy to read and handle. You can carry each single volume about with you until you have mastered the subject it contains. Written in the form of questions **you** would ask and the answers to them — in plain, practical, everyday language, complete, concise, authentic and to the point. Over 3200 pages and more than 4,000 illustrations.

Read These Testimonials

"Any Electrician, Operating Engineer, or Student who wants to do his own construction or further advance himself in the Electrical field should have a set of these books."
JOHN KELLEY
116 Union St., Newark, O.

"For the man not getting a college training and even in that case, I can sincerely say I do not believe there is a better set of books in the market today." LLOYD D. HUFFMAN
Dayton, O.

"We consider Hawkins Electrical Guides the most compact and complete set of electrical references in the market."
NOGGLE ELECTRIC WORKS
Monterey, Cal.

"Hawkins surely knows the art of condensing information." ELBRIDGE F. BALL
Buckland, Conn.

10 NUMBERS IN ALL

How the Blind May Read by Sound

By Professor F. C. Brown

THE Phonopticon is an instrument that translates the varying light composites, particularly those of the printed page, into characteristic sound composites. The illumination from the printed page varies in intensity, form and sequence. The inventor of this valuable scientific device set out to translate this varying character of light, through electrical means, into sound impressions varying in pitch, intensity and sequence.

The only fundamental difficulty to be overcome was that of the production of some very light-sensitive agent which could be used in small size units. It was required that this agent should instantly change its electrical resistance whenever the light intensity varied. The ordinary selenium cells, where the amorphous selenium was crystallized in mass aggregates, were hardly satisfactory for three reasons. They were first of all insufficiently sensitive, were necessarily too large to properly discriminate printed letters and they lacked the stability and uniformity required. The inventor had the problem of the aural interpretation of the printed page through mechanical means casually in mind for three years before he succeeded in obtaining the specially sensitive crystals to do what the rods and cones do for the human eye.

Finally he succeeded in producing isolated crystals of selenium, such as are shown in Fig. 1, which were large enough to be placed in separate electrical currents and which were small enough to receive the impression from a fractional part of the smallest ordinary print. The crystals were grown by special means of sublimation of the vapor of selenium, some of the most sensitive varieties requiring months for formation. In Fig. 1 A represents selenium crystals of the monoclinic system, B hexagonal crystals and C some interesting growths of crystals of selenium. These crystals further were found to be stable and extremely sensitive to light. They are more than a hundred times more sensitive than the most sensitive standard selenium cell. One of the crystals will, with a sensitive galvanometer, respond to a light only *three-millionths* as intense as the most sensitive thermopile. Experiment shows that with one of these crystals and a 24-inch telescope *it is possible to detect the presence of a 16-cp. carbon lamp at a distance of more than 1,000 miles.*

Marvelously Light-Sensitive Electrical Device Perfected by Prof. Brown by Which Blind People May Read by Sound.

Thus these crystals in the phonopticon correspond in function and sensitiveness to the rods and cones of the human eye. The electric currents that pass through the crystals correspond to the nervous impulses that pass in the optic nerves. It might some day be possible, in certain cases of blindness, to connect these varying electric currents directly to the optic nerves and thereby get stimula similar to ordinary light stimula. However, the inventor chose a much easier road to the brain centers of the blind. He elected to transform these varying electric currents into corresponding varying sound characters and thereby *let the blind see by hearing.* The arrangement of the electric circuits and the selenium crystals is shown in a conventional way in Fig. 2. The crystals are placed in combination Wheatstone bridge circuits. The light from the white page 6 is focused on a line of crystals 1 by a lens 5. The blind reader adjusts a sliding resistance 8 for each crystal until there is no sound heard. He can ascertain the currents from each crystal by the frequency of interruption of the current, i. e., by the pitch associated with each.

The printed letters are illuminated successively by a narrow ray of intense light which travels across the page. The image from the lens acts upon a parallel group of crystals, which control different frequencies

DID you ever stop to realize how many thousands of the soldiers now battling for their lives in Europe's tragic catastrophe will return home blinded for the rest of their lives? Besides there are many thousand blind in our own country. To all these unfortunates there seems to be a new hope held forth, for by properly combining selenium and electricity Professor Brown has seemingly solved the problem of how the blind shall see, even though their eyes be closed. Would this invention not be well adapted to curtail eye-strain for those who have perfect vision?

in the telephone receivers. The interrupters (18, 18, 18), in series with each crystal, give a different distinct pitch for each crystal affected.

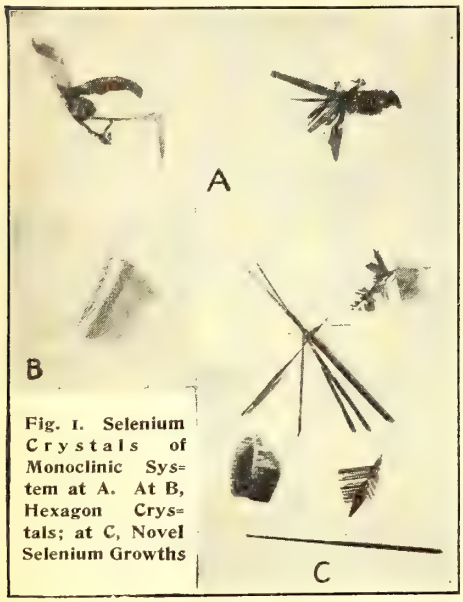

Fig. 1. Selenium Crystals of Monoclinic System at A. At B, Hexagon Crystals; at C, Novel Selenium Growths

These electrical impulses, thus controlled, are converted into sound waves of a specific pitch or note by a resonator provided in each telephonic receiver. Three receivers are here used, their number corresponding to the number of crystals employed, which may vary from one to four. So that three receivers may be used at one time, there is incorporated in one receiver shell two resonator and diaphragm mechanisms, as seen in Fig. 3. Thus each "part" of a printed letter affects a certain crystal, and through it upon a separate interrupter and resonator (receiver). As the successive parts of a letter enter the lighted field before the lens (and crystals), the changes resultant are simultaneously manifested by a change in the pitch of the note.

When the little box containing the lens and the crystals is moved over the page a series of notes are heard in varying sequence, loudness and rapidity. The blind person soon learns the combination of notes and intensities produced by each letter and, in fact, by each word. One blind person was able after 20 minutes' practise to illustrate on the pipe organ the alphabet of the phonopticon.

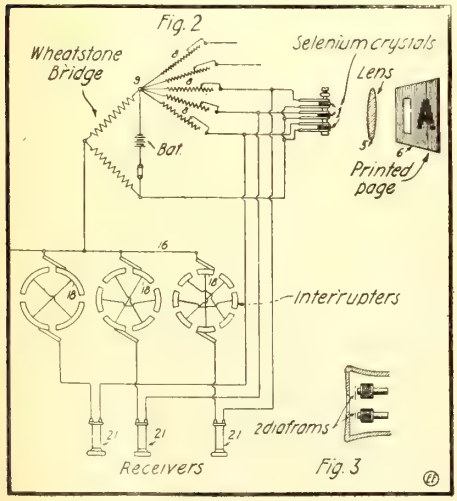

Diagram of Apparatus Enabling Blind to Read Electrically.

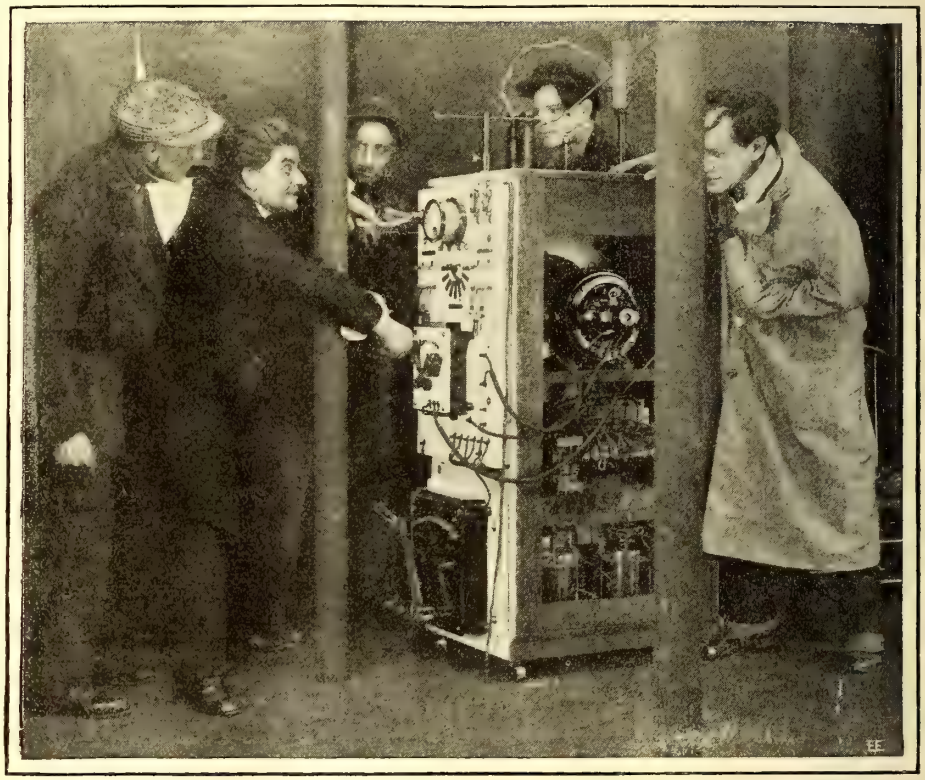
Electro Ray Projector, a Movie Concoction

Pearl White, "Pathé's Peerless Pearl," as she is called, still works her magic on the motion picture fans, and is undoubtedly the most popular little lady that has come to gladden the screen since—well, since she was last seen as the ebullient Elaine in company with Edwin Arden as the wicked Wu Fang, and Arnold Daly as the clever Craig Kennedy. She is still beautiful, blonde and beatific, and just the sort of person romantic things couldn't help happening to.



After being rescued by that mysterious avenger of wrongs, known to the underworld as "The Laughing Mask," and returned to the father she was kidnapped from when a child, she is again threatened by the sinister master criminal Legar, alias "The Iron Claw." Legar's purpose is to wreak vengeance on Enoch Golden, the girl's father, who, years before, finding Legar, then his friend, unfaithful, had the latter's face seared with white hot irons and his hand crushed in a vise.

To intimidate Golden into returning his daughter to his (Legar's) clutches, the master criminal with the help of Stein's "Electro Ray Projector," a deadly instrument, sets fire to many of Golden's properties and threatens further mischief should his demands not be acceded to. Marjorie, the daughter, seeing that she is the cause of great misfortune to her father, voluntarily returns to "The Iron Claw."

But, by the looks of the thing, Legar won't have such easy sailing, for Davy Manly, Golden's secretary, has her interests at heart, and that other mysterious agent, "The Laughing Mask," promises to give further account of himself in the next chapter called "The Cognac Cask."

ELECTRIC 'BUSES IN ARABIA.

It is proposed to replace the horse-drawn carriages at Aden, Arabia, with 'buses using electric batteries. A 'bus that will carry six or seven passengers at a regular fare of about 12 cents from Steamer Point to Crater, about 5 miles, is expected to wrest all the business from the old-time pony carriages. The electric type is favored because of the high price of 36 cents a gallon for gasoline.

A "Thriller" from the Movies, When the Villain Demonstrates His Electro Ray Projector.

CONGRESS INTERESTED IN RADIO TORPEDO.

Wireless control from an aeroplane of a coast-defense torpedo has been perfected, it was learned recently, and patents are included in the Hammond radio-controlled torpedo rights, for the purchase of which the Navy Department has asked Congress to appropriate nearly a million dollars.

Aeroplane control, navy officers explain, makes it possible for the operator to guide the radio torpedo through the water from any height, air bubbles from the compressed air motor of the torpedo giving him a certain guide by which to steer it against a ship's hull. By use of powerful glasses it has been possible heretofore to control the torpedo from shore to a distance of nearly 10,000 yards, but the aeroplane device now will make the missile effective to the full range of its motor capacity, or even far at sea if the torpedo is launched from a swift motor boat within sight of an enemy ship.

WHAT 1 CENT OF ELECTRICITY WILL DO.

Operate sewing machine two hours.
Keep six-pound iron hot 15 minutes.
Heat electric curling iron 14 times.
Percolate four cups of coffee.
Lift 100 gallons of water 100 feet.
Give light of 75 candles for one hour.
Toast bread for six persons.
Operate luminous radiator for eight minutes.
Warm baby's bottle twice.
Cook Welsh rarebit in chafing dish.
Keep heating pad hot two hours.
Heat 8-inch electric stove eight minutes.
Operate 12-inch fan two hours.
Vulcanize four automobile tire patches.
Keep foot warmer hot one-quarter hour.
Raise passenger elevator five stories in a minute.
Operate electric griddle eight minutes.
(Calculating current at 10 cents per kilowatt-hour rate.)

Searchlights and Radio Aid European Warriors

GERMAN SEARCHLIGHT THROWS BEAM EIGHT MILES.

The German military authorities, with proverbial thoroughness, have appropriated every branch of science available for the most expeditious conduct of scientific warfare, both on land and sea. This is exemplified in a marked manner by their very extensive employment of powerful electric searchlights, which are kept continually flashing through the night atmosphere in search of the enemy.

The searchlights are often used in groups of considerable numbers when a night attack is to be made by infantry or trenches are to be stormed. In other cases they prove extremely valuable to the artillery range finders, as otherwise it is often very difficult to make effective use of this arm of the military service at night.

In the illustration herewith a German officer is making observations by means of one of their extremely efficient searchlights recently developed for use in the famous Flanders region, which extends for miles. It is possible for these searchlights to throw a strong beam *eight miles* away, even on cloudy nights.

A Powerful German Army Searchlight in Action at Night in the Famous Flanders Region.

ELECTRICALLY HEATED UNIFORMS NOW.

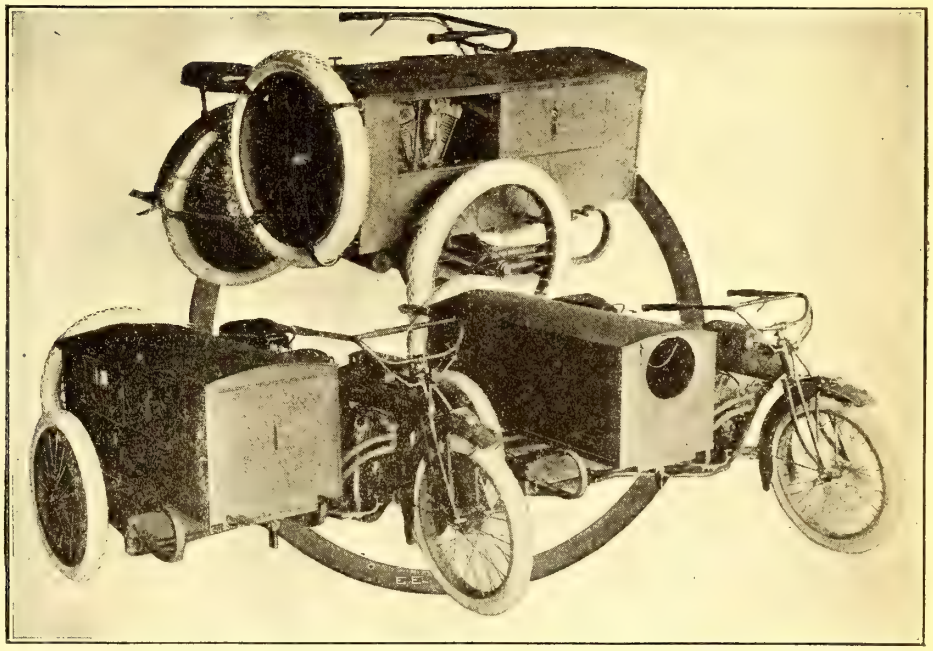
Austrian soldiers will not suffer from cold weather if the electrically heated garments which have just been invented by the professor of electricity at Innsbruck University prove feasible. The essential feature of the professor's invention, according to the Austrian newspapers, is a method of weaving electric heating threads into soldiers' pants and coats and then connecting the threads with a battery or supply wire at a distance of from 100 yards to a quarter of a mile. It is asserted that the current can be regulated so that any number of soldiers in the trenches can be kept warm simultaneously.

EDISON OPENS ELECTRIC SCHOOL.

An experimental school of electricity for the officers and men of the United States navy has been opened at Orange, N. J., by Thomas A. Edison, chairman of the Naval Advisory Board, acting in co-operation with Secretary Daniels. The men of the submarine flotilla who have to do with complicated electrical equipment will receive their training first.

Fourteen officers and 30 men from Quincy, Mass., and the New York navy yard recently finished a course.

A WIRELESS MOTORCYCLE FIELD STATION.



A number of "Indian" motorcycle wireless stations, which may be moved at will from point to point, have just been completed at Springfield, Mass. Besides the original instrument van and the machine to haul it, an additional feature is another motorcycle and van which serves to carry poles, wires, tent, blankets and other paraphernalia for camping, thereby making each group of the service independent of tall trees and houses on which the field wireless formerly relied for temporary headquarters.

The wireless camp resembles somewhat a battery of field artillery in its plan, having essentially one motorcycle unit which hauls the wireless sending and receiving equipment either in a side carriage or trailer, corresponding to the field piece, and another motorcycle hauling the service van, corresponding to the ammunition caisson. Having two machines in each set, the service consequently embraces 10 motorcycles and vans. The wireless operator rides behind the driver of the motorcycle on a spring tandem seat.

Power for the wireless station is furnished by a 5½ horse-power twin cylinder engine, set up in one compartment of the van, which drives by direct chain drive a small two-in-one receiving and sending electric generator. The varying speeds at which the engine or generator may revolve are transmitted through a direct-drive chain, running on a compensating sprocket at the shaft of the generator, which insures smooth running. On its sending side the generator develops 700 volts, 2.6 amperes, being capable of sending a message nearly 500 miles by wireless, and on the receiving side 110 volts, 2.7 amperes for the audions. The operator's instruments are in the forward compartment of the van and when a halt is made, to set up communications, he removes the keyboard some distance from the power plant in order to hear better. He regulates the power of the engine by magnetic control of the throttle. Starting of the engine is accomplished by turning over a hand lever.

A supply of gasoline sufficient for 12 to 24 hours' continuous operation of the plant may be carried in the regular tank and three reserve tanks. The capacity of the gasoline tank on the motorcycle is sufficient for 100 miles of travel.

The weight of motorcycle and wireless van is about 1,176 pounds. The box is 4½ feet long, 21½ inches wide and 20 inches deep.

Type of Motor-Cycle Radio Pack Sets Now Being Built for Rapid Transit Over Battlefields.

Historic Telephones

WHEN we step into the nearest telephone booth to-day and without the slightest trouble or delay are swiftly connected with our desired party, perhaps hundreds or even thousands of miles away, we do not always, or, in fact, rarely, stop to think of the vast amount of labor and gray matter expended on the telephone in the past 40 years, during which time it has slowly but surely developed into one of the greatest industries in the world's history.

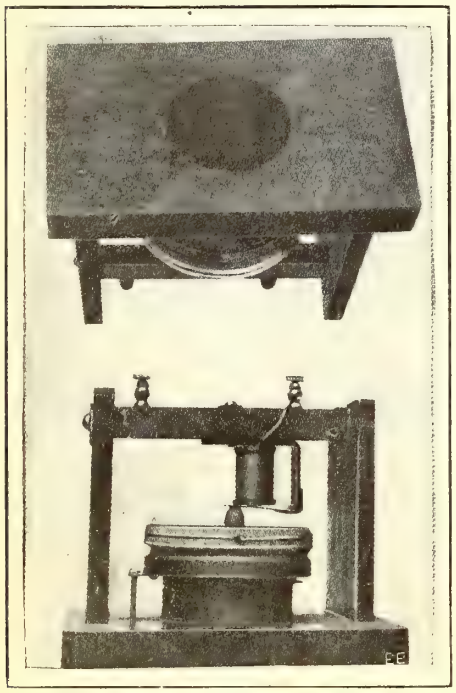


Fig. 2. Two Views of the First Bell Telephone Model, Utilizing a Diaphragm of Gold-Beater's Skin.

We present herewith a number of interesting illustrations depicting the early models of the speaking telephone as perfected by Alexander Graham Bell and his assistant, Thomas A. Watson. In the year 1874 Prof. Bell was intensely interested in developing a harmonic telegraph instrument. The appearance of one of these devices is perceived at Fig. 1. These consisted of an electro-magnet supported on a yoke, and on the upper end of this yoke there was clamped a steel rod or spring of a certain musical pitch. It was Bell's idea that if, say, six of these instruments were hooked up to a common two-wire circuit, then it would be possible to transmit six distinct telegraphic messages over this line simultaneously, if each of the transmitter springs were of a different musical pitch. Each spring at the transmitter end of the line carried suitable contacts, so as to make and break the line circuit current, and, moreover, each transmitter spring would vibrate at a certain frequency, owing to its being tuned in the manner described.

The discovery of the speaking telephone is directly allied with this seemingly unimportant piece of apparatus. This wonderful event occurred during a test of the musical telegraph apparatus conducted by Messrs. Bell and Watson on the afternoon of June 7, 1875, at Boston.

It was Watson's task to consecutively and repeatedly set the transmitter springs going on these musical telegraph instruments, while Bell at the other end of the line was busy retuning the receiver springs, one by one. This he usually accomplished by listening to each spring as he held it near his ear.

"One of the transmitter springs I was attending to stopped vibrating," relates Mr. Watson, "and I plucked it to start it again. However, it did not start according to schedule and I kept on plucking away on it, when suddenly I heard a shout from Bell in the next room. And out he came with a rush, demanding: 'What did you do? Don't change anything; let me see!' I showed Bell just what I had done, and the fact of the matter was that the make and break contact point of the transmitter spring I had been trying to start had become welded together, so that when I had snapped the spring the circuit had remained unbroken, while that strip of the magnetized steel, by its vibration over the pole of its magnet, was generating a current of electricity that varied in intensity precisely as the air varies in density within hearing distance of that spring. The undulating current so produced had passed through the line wire to the distant receiver, which, fortunately, was a mechanism that could transform that current back into an extremely faint echo of the vibrating spring which had generated it."

Bell took full cognizance of this startlingly scientific fact so suddenly demonstrated before him and directly he had built the first telephonic instrument ever devised. This had the appearance illustrated at Fig. 2. The framework was made of wood, while the mouthpiece was formed in the frame itself, as perceived. At the inner end of the mouthpiece chamber was tightly fastened a diaphragm of gold-beater's skin. The center of this diaphragm was joined to the free end of the spring on one of the harmonic instruments. The idea here was to force the steel spring to follow the vocal vibrations developed by the air currents impinging against the diaphragm primarily and thus to generate a current of electricity that would vary in intensity as the air varies in density during the utterance of speech sounds. The first sentence ever spoken over this crude but marvelously correct telephonic device was that spoken by Prof. Bell: "Mr. Watson, please come here; I want you."

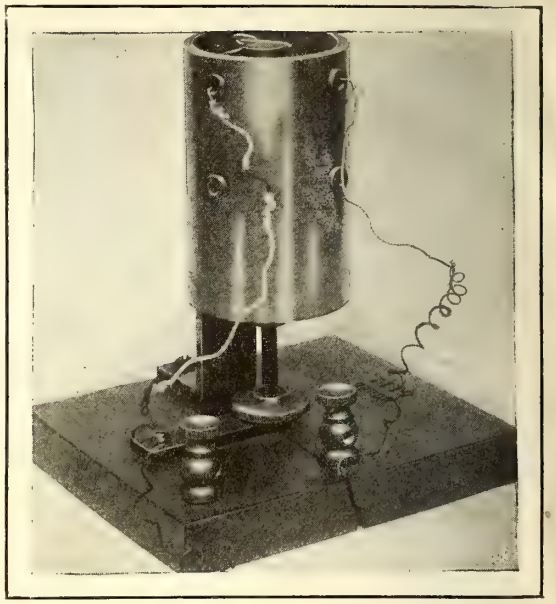

Fig. 4. Original Model Telephone Receiver Exhibited at Centennial Exposition.

Hundreds of different ideas were tried out in the early days of the telephone, such as various sizes and kinds of diaphragms, magnets, mouthpieces, ad infinitum.

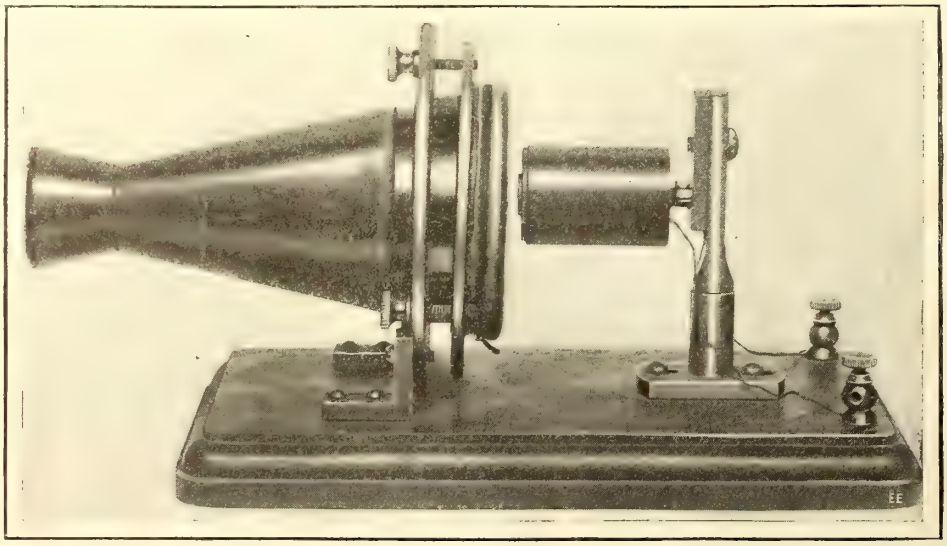

Fig. 3. The First Magneto Telephone Model (for Transmitting) Exhibited at the Centennial Exposition, Philadelphia, in 1876.

At the Centennial Exposition held at Philadelphia in 1876, and although the telephones of Prof. Bell were hardly ready for a practical demonstration on such an auspicious occasion, he finally was persuaded to exhibit a set of apparatus. The instruments were finished up in the best manner possible and worked very well indeed, considering that but a small amount of research work had been carried out to develop them at this time. The original Bell magneto transmitter exhibited at this Exposition was of the type illustrated at Fig. 3. The receiver or reproducer of the spoken word appears at Fig. 4.

The transmitter demonstrated on this occasion employed a non-metallic diaphragm stretched over the inner opening of the

mouthpiece chamber, and to its center was secured a small piece of iron in the form of a disk. When the voice was projected

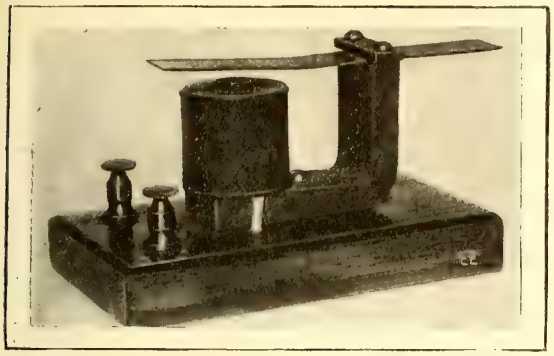

Fig. 1. Forerunner of the First Telephone; the Harmonic Reed Telegraph Devised by Prof. Bell.

into the mouthpiece the undulating air currents caused the diaphragm to vibrate in the same manner as it does in the instruments used to-day and corresponding electric currents were set up in the magnet coil mounted directly back of the diaphragm. These currents passed out over the line wire to the receiver of similar pattern, shown at Fig. 4.

Many distinguished visitors to the exposition heard the telephone talk and were astounded beyond words. The Emperor of Brazil happened to see the telephone on exhibition and asked for a demonstration. He listened intently at the receiving end of the circuit and was utterly astonished when the insignificant-looking device sitting on the table before him gave forth actual speech. He could only exclaim: "My God! it talks."

Sir William Thompson also tried the telephone, which, it must be remembered, was very new, even to the scientists of the day. This gentleman in his report on the telephone after his return home said: "I need hardly say that I was astonished and delighted, and so were others who visited the exhibition and verified it with their own ears, the electric transmission of speech."

The telephone began to develop shortly after this at a fairly decent rate and in April, 1877, the first outdoor telephone line was run between Mr. Williams' office at 109 Court street, Boston, and his house in Somerville. Fig. 5 depicts what was called the box type telephone. This was used in the Boston-to-New York test, which, after quite a good deal of experimenting and changing of line wires, etc., culminated in complete success.

In the first telephones perfected for single circuits no method was available for calling the party at the other end of the line when one wished to carry on conversation with him. Therefore when the telephone began to spread out and longer lines were in vogue, and especially when the first exchanges or central offices were started, some form of calling device became absolutely necessary.

It was common in the earliest instruments installed for the party doing the calling to thump against the diaphragm of the apparatus with his pencil. Sometimes the pencil was not handy, so the next step was to use a sort of thumper. This is shown at Fig. 6. At the left of the apparatus, as observed, a small "calling" push button projected from the front of the cabinet. When this was pressed it actuated the small hammer, and in this way the thumps against the diaphragm were transformed into an undulating electric current which passed out over the line, giving rise to corresponding diaphragm "thumping" notes at the receiving instrument. Thus did the early 'phone subscriber notify the party wanted at the opposite end of the circuit that they were wanted at the instrument. To-day your 20th century 'phone user wants "instantaneous service" and no half-way business about it. Did you ever stop to contemplate what havoc would ensue in the present business world with its thousands of diversified ramifications, if all the telephone lines were suddenly severed?

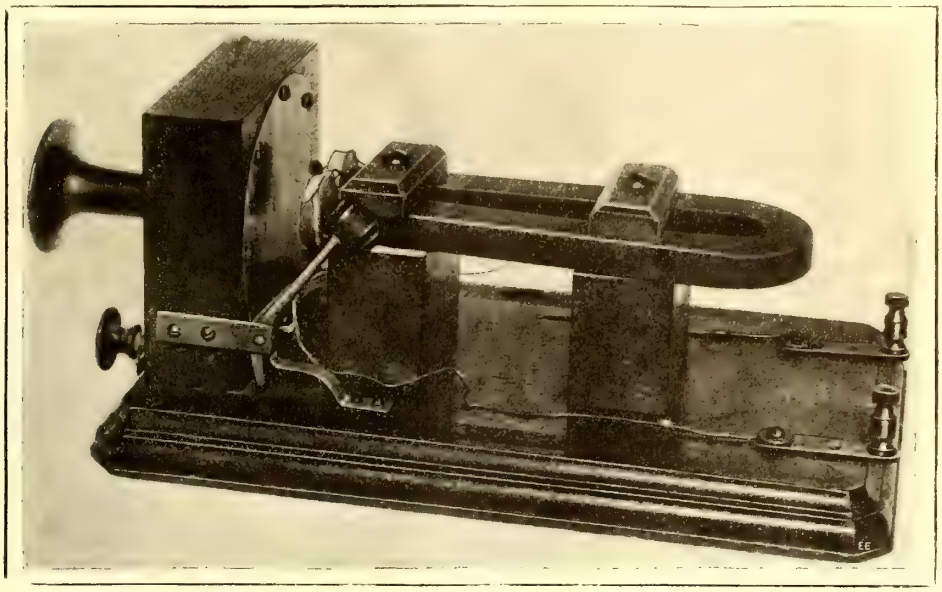

Fig. 6. One of the First Practical Telephones Developed. It is Equipped with a Calling Hammer, as Observed, Which "Thumped" the Diaphragm and These Signals, Reproduced at the Receiving Instrument, Notified the Party Wanted, but Not in the Most Gentle Manner, to be Sure.

"The 'Watson thumper' brought me only a fleeting fame," says its inventor, "for I soon superseded it by a magneto-electric call bell that solved the problem, and was destined to make a long-suffering public turn cranks for the next 15 years or so, as it never had before, or ever will hereafter.

"Perhaps I didn't have any trouble with the plaguey thing! The generator part of it was only an adaptation of a magneto shocking machine I found in Davis' Manual of Magnetism and worked well enough, but I was guilty of the jingling part of it. At any rate, I felt guilty when letters began to come from our agents reciting their woes with the thing, which they said had a trick of sticking and failing on the most important occasions to tinkle in response to the frantic crankings of the man who wanted you. But I soon got it so it behaved itself and it has been good ever since, for Chief Engineer Carty told me the other day that nothing better has ever been invented, that they have been manufactured by the millions all over the world, and that identical jingler to-day does practically all the world's telephone calling.

"For some reason, my usual good luck I presume, the magneto call bells didn't get my name attached to them. I never regretted this, for the agents, who bought them from Williams, impressed by the long and narrow box in which the mechanism was placed, promptly christened them 'Williams' Coffins.' I always thought that a narrow escape for me! The first few hundreds of these call bells were a continuous shock to me for other reasons than their failure to respond. I used on them a switch, that had to be thrown one way by hand, when the telephone was being used, and then thrown back by hand to put the bell in circuit again. But the average man or woman wouldn't do this more than half the time, and I was obliged to try a series of devices, which culminated in that remarkable achievement of the human brain—the automatic switch—that only demanded of the public that it should hang up the telephone after it got through talking. This the public learned to do quite well after a few years of practise."

So the marvelous telephone, once called a device of the devil, has happily prospered to make man's work easier than ever before.

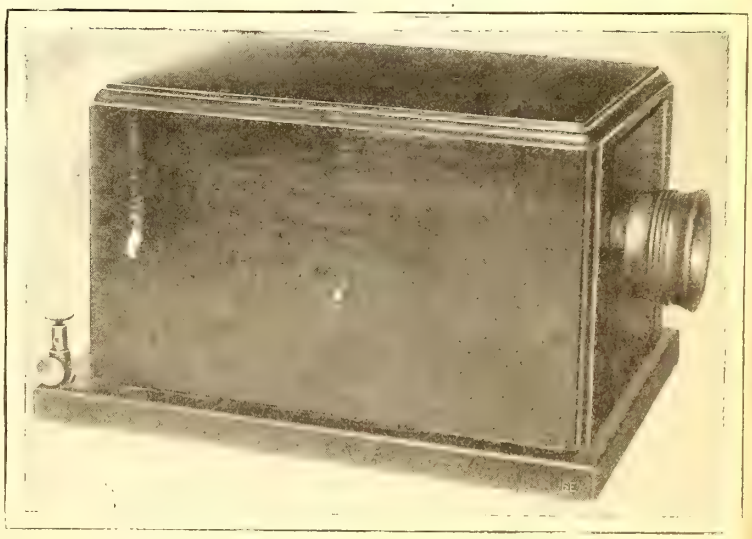

Fig. 3. Early "Box" Type Telephone Used in the Boston-to-New York Tests. A Wonderful Achievement in Its Day.

Lightning, Its Effects and How to Avoid Them

With the Approach of Summer it Behooves Us to Learn All We Can on the Subject of Lightning and Protection from Same. The Safest Place for Individuals During Thunder Storms Is Covered Herein.

By H. Winfield Secor

NO electrical discharge ever produced by mortal man can approach the awe-inspiring and wonderfully spectacular electrical displays taking place in nature and which we know as *lightning*. Lightning is an electrical discharge caused by the air breaking down where two opposite electric charges exist on two adjacent clouds or between the earth and a cloud.

"The prime cause of lightning is the sunbeam," says Prof. West Dodd. The cloud does not gather electricity out of the air as many people imagine. The electrical energy in the cloud is due to sun heat which brings about the rapid evaporation of water.

Heat is one of the nine forms of energy, and when evaporation of water takes place, the sun heat that caused the evaporation changes into one of the other forms of energy. The little globules float away, each carrying its own little quantity of "energy" or "strain" on its surface, and when the countless billions of these energized, invisible globules rise to the sky, where the cold of elevation rapidly condenses them into raindrops, this energy is released in the form of electricity, ready to give back the energy of the sun condensed into lightning flashes.

Our philosophers try to teach us this: "Before the house is struck by lightning an electric strain is placed upon it." That is, a condition has been coaxed into it, and it is this condition we have to deal with if we would prevent it from bursting into a lightning explosion.

But if a fog extended from the cloud to the earth, this condition would not exist, as the electricity easily reaches the earth through the fog by conduction and thus no lightning is produced.

Also you possibly remember that you never saw lightning on a foggy day, but when the air is dry the earth directly beneath the charged cloud is electrified in sympathy with the cloud and tries to discharge to the cloud the same as the cloud tries to discharge to it, and a great electrical strain is set up between the cloud and the earth.

The air is a poor conductor of electricity; and things that stick up from the earth into the air, like houses and barns, become discharging points for the earth's electricity, and in this way the house really prepares to be struck.

So the lesson we wish to impress here is this: Lightning is due to causes. Electricity first gets in its work and loads up a cloud. Then this cloud fixes up things on the earth and induces an opposite electric condition, and the two electrified surfaces strain and pull on each other; then when the strain becomes great enough so that the air cannot resist any longer, off it goes with an explosion through the house, and probably the undertaker has a job on his hands.

Having shown as clearly as possible in so short a time the cause of lightning and how the flash is brought about, let us consider briefly the remedy or how the stroke may be averted.

Let us begin by calling to mind that there are some things lightning will not strike. There is a reason for it. "Chance" is unknown in the operation of nature's forces. There is no safer place on earth from lightning than in a steam engine or in a railroad coach. No one was ever known to be injured by lightning when in a railway train. Lightning will not strike the business part of a big city. The tall skyscrapers of our large cities are immune from lightning, and insurance companies never have any losses from lightning on any building with metallic sides and frame work of iron and steel. It will not strike a modern battleship, on account of the material of which it is constructed, and a steel windmill tower is never injured by lightning. The reason is that every one of these objects is its own lightning rod. They need no further protection.

But there are things lightning will strike. Lightning will strike a country home, or a home in the suburban part of the city. Lightning will strike a barn or a church or a schoolhouse or a tree or a stack or an animal, especially if near a wire fence. All of the lightning losses our insurance companies have to pay are on this class of risks, and a man has to be blind almost purposely, not to see room for thought in these observations.

Where is the safest place in the house during a thunderstorm? Your metallic bed. This may surprise you, but at night the safest place is sleeping in an iron or brass bed. To stand by the metal bed is very dangerous, for you are taller than the bed, but lying on it is safe, as the bed extends above and below you, and the current will not have the bed to pass through you, also the current will not leave it, but the walls above the bed and the floor beneath would be ripped to pieces. Contrary to popular opinion, feather beds are not safe to sleep on, unless they are in a metal bed frame. If you are sleeping on steel springs in a wooden bed, the springs would save you if you are in the center of the bed, while the bed posts would be split to pieces and possibly the bed would be set on fire. During the day the safest place is in the center of the room if away from the stove. Open doors and windows make no difference, as lightning does not come in at open doors, as many people imagine, says Prof. Dodd.

Referring to the illustrations herewith a particularly heavy lightning discharge is observed at Fig. 1. A series of multiple flashes emanating from a cloud of high electrical activity is perceived at Fig. 2. The illustration at Fig. 3 shows a lightning bolt striking in a field near a building. This is a particularly bad form of discharge and its path is quite direct, as may be observed. Fig. 4 illustrates a rather common form of lightning discharge which is very beautiful to be sure. In this case the lightning tends to discharge between one cloud and several other clouds, providing in this way a most spectacular effect, lighting up the whole sky. Very little thunder accompanies such discharges as this one for the lightning takes place so far above the earth that the thunder (sound caused by the lightning flash), or at least the greater portion, does not reach our ears. The illustration at Fig. 5 shows the lightning flashes often observed in the country or suburban districts. The display in this case is particularly severe, as there are two distinct flashes occurring simultaneously. The heavier discharge seen in the distance has no doubt proved very disastrous, judging from its appearance, to any building or structure of similar nature which might have been in its path.

In many instances the lightning simply strikes the earth without harming any one or any structure such as a house or barn. All electrical transmission, telegraph and telephone systems suffer to a greater or less extent from lightning during the summer months. Suitable protective measures have to be taken accordingly. Lightning protective apparatus such as minute spark gaps and the like are installed on such circuits, with proper ground connection attached to the gaps, etc., so that any heavy current produced on these lines by lightning discharges will pass to the earth without entering the switchboards, thus burning out delicate and expensive apparatus, besides often proving fatal to human life.

With regard to the potentials of light-

Fig. 1. A Particularly Heavy Lightning Flash.

Fig. 2. A Series of Multiple Lightning Flashes Emanating from a Cloud of High Electrical Activity.

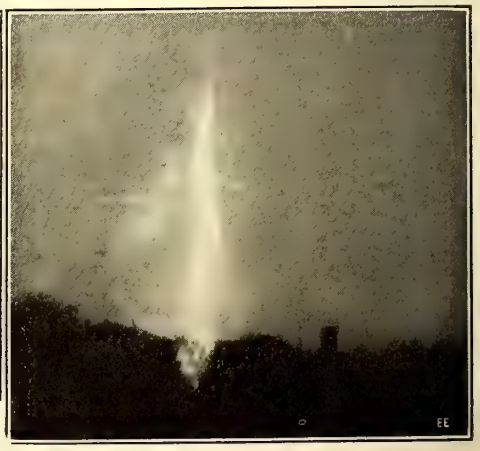

Fig. 3. Lightning Bolt Striking in a Field.

ning flashes but little more than estimates are available. The potential required to cause a flash of lightning a mile long has been estimated by Lodge to be 5,000,000,000 volts; using as a basis the breakdown voltage of air, which is about 30,000 volts per cm. Although this seems rather improbable it can be shown by calculation, based on experimental evidence at hand as to the electric charges of falling rain, that such voltage conditions may be realized. Prof. Trowbridge, however, has cast doubt over the validity of these figures by means of experiments with voltages exceeding a million, which seem to indicate that with long air gaps and extremely high potentials, air may exhibit properties quite different from those shown under the voltage conditions which have hitherto been realized. In designing a system of lightning rods the only potentials which need to be considered are those set up in the system itself.

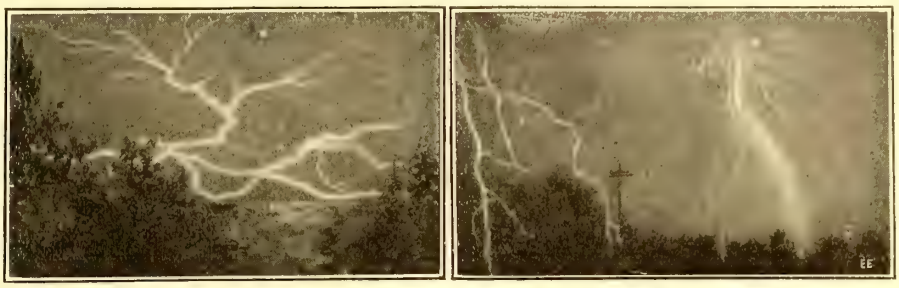

Fig. 4. (Left), Illustrates a Rather Common Form of Lightning Discharge Often Seen Over Bodies of Water. Fig. 5 (Right), Double Flash, Often Observed in Suburban Districts.

The well-known flickering of lightning flashes, which is visible to the unaided eye, indicates that a flash of lightning does not always consist of a single discharge of electricity, but, on the contrary, consists usually of a number of successive discharges which follow each other with very short time intervals between them. By standing where the light from a flash does not blind the eyes, an observer can detect the successive discharges for each complete flash of lightning, the number of which varies, for different flashes, from 2 or 3 to 10 or more.

The frequency of a stroke of lightning has been calculated by Emde, by assuming (1) a circular conducting cloud and a circular portion of the earth's surface situated symmetrically below it; between these the lines of force are normal to both; (2) a concentric cylinder occupied by incandescent gas between the cloud and the earth; (3) that the current density is the same in each cross-section of this cylinder, i.e., that no waves exist along the gas column. By making additional assumptions in regard to the diameter of the cloud and flash, Emde finds a frequency of from 2,000 to 8,000 cycles per second, or an average of 5,000 cycles. There is some doubt, however, as to the validity of Emde's assumptions, and his results should, perhaps, be taken only as in some degree confirmatory of the opinion which more or less generally is held that lightning is, in effect, an electrical discharge of medium frequency; that is, *hundreds of thousands of cycles per second;* as distinguished from low frequencies of a few hundreds of cycles per second, or high frequencies to a million or more cycles per second; and in most cases is of sufficiently steep wave front to excite secondary high-frequency phenomena, even though it may be so rapidly damped as to be practically a unidirectional discharge. To state definitely what ranges the frequency of lightning discharges may cover, however, requires that much more experimental work be done.

From data in several fire tables covering a period of 19 years prior to the year 1903 given in a publication issued by the Government on "Lightning and Protection from Same," there is shown that out of 146,618 fires from all causes in barns, stables and granaries, there were 14,968 caused from lightning. These figures include the total of all fires both known and unknown. The percentage of fires caused by lightning having been 10.2 per cent. The per cent. of fires from known causes and which were due to lighting comes up to 21.5 per cent. At any rate and especially from statistics obtained by various insurance companies in the Central and Western States, where there are a great many isolated barns, dwellings and other buildings, owing to the large farming sections, there is a great risk incurred during the summer months by lightning destroying or partially destroying such structures and also killing live stock. Animals are often killed by coming in contact with charged fence wires. In the Eastern part of the United States not much attention is paid to protection from lightning as in general there are a greater number of cities and also steel frame buildings are more in vogue. Such buildings and also where dwellings or other edifices are gathered into solid blocks and in addition provided with metal roofs connected to the ground through leader pipes, etc., the lightning has very little chance to create any disruptive discharge, but instead is dissipated noiselessly into the earth through the greater surface leakage thus provided for it.

In the case of isolated frame structures or other buildings, not provided with steel framework, there is only one safe method to follow for the protection against lightning, and this is to install proper lightning rod systems. Every isolated dwelling, barn and other outbuildings of any consequence should be protected in this way from the ravages of nature against the electrical demonstrations of which it is not safe to gamble or bet.

The safe way is the best way, and it seems as in many other lines of human endeavor the modern systems of *rodding a house,* as it is called, for lightning protection has eliminated the old-time glass insulator, which was ridiculously small and in fact, if anything, conduced to the disruptive or flash discharge of the lightning current.

Regarding lightning protection by means of metal wires or rods properly placed over a building, and particularly at all of the highest points of the roof of same, such as chimneys or gable peaks, this is well covered in what is known as "The Phoenix Fire Office Rules for Lightning Rods."

Sir Oliver Lodge, the famous English scientist, has made an exhaustive study, in so far as possible, of lightning and its effects on buildings toward the end of protecting them by metal wires properly erected over or installed on the building itself. It has been found that to guarantee the utmost protection in this direction, the building should be literally enclosed in a heavy cross-connected wire frame work resembling a bird cage. It is manifestly quite impossible to go to any such expense or to have a building so thoroughly covered as to become unsightly with any such arrangement as this.

In a modification of this system for an ordinary building, a sufficient practical approach to ideal conditions can be attained by taking advantage of the extent of metal work outside it and adding a few other conductors, so as to surround it and imitate roughly a metallic inclosure. Under expert supervision this can be accomplished by utilizing the rain-water pipes and gutters as part of the system. Joints in the pipes and gutters act more securely when "bonded" together or made electrically continuous. The ordinary conductors must be fixed in addition, and the whole system of pipes, etc., together with the special conductors, may advantageously be interconnected by a horizontal conductor taken round the buildings, either two or three feet above the ground level or buried in the ground.

The complete system should then be efficiently connected to earth at several places.

A building with trees adjacent to it, or dominated by a steeple or other lofty building, must not be considered as immune. A discharge is seldom solitary, along one single path; it is often an assemblage or bush of flashes, and all points in the neighborhood are liable to be struck by some of the subsidiary or accompanying discharges. Even underground cellars have been so invaded.

Material of conductor. Material should be of copper tape at least 1 inch by ⅛ inch, or of a stranded copper rope of not less area; no cable to be smaller than that composed of seven strands, each of ⅛ inch diameter, or of soft iron cable, properly galvanized or sheradized; the total sectional-area of iron cable need not be greater than that of copper, except for chemical reasons and permanence. In inaccessible places, and atmospheres where chemical corrosion may be feared, copper should be used of larger sectional-area than 1 by ⅛ inch.

Conductors should be run in as direct a line to earth as convenient, and sharp bends and joints avoided; they should be kept a certain distance away from the walls. The object of keeping conductors a certain distance away from walls is to prevent accumulation of dirt, and to avoid sharp bends when passing over cornices, etc., *but they must not be insulated from the walls.*

For tape conductors all joints must be carefully soldered and made electrically and mechanically continuous, i.e., screwed together or clamped. Stranded cable conductors should be connected by lineman's joints and soldered or united by a special joint box. After the strands of the cable are twisted together, the box should be filled in with molten solder.

Elevation rods should be of solid copper or galvanized iron of ample cross-section and fixed at least two feet above that portion of the building to which they are attached by a sleeve joint soldered and pinned, or by means of a box-joint filled with solder and pinned. In the case of chimney stacks, the rod must extend at least one foot above the highest chimney in the group which forms the stack.

Hold-fasts should be of gun metal or brass for copper conductors or of malleable iron for iron conductors and let into the wall in such a manner as to support and keep the conductor away from the structure at such a distance as will avoid any-

(*Continued on page* 737.)

A "Hook-less" Telephone Receiver the Latest

By Samuel Cohen

ALL telephone instruments now in use require a "hook-switch" or its mechanical equivalent upon the proper manipulation of which, among other things, depends the efficiency of the telephone service. All calling and clearing-out signals, without which it is impossible to operate a modern telephone exchange service, are now transmitted by the subscriber in the act of removing his receiver from and restoring it to the *telephone hook*. This is pivoted or otherwise mounted in bearings in such a manner as to make alternate contact with upper and lower spring connections, designed to open and close the respective electrical circuits. If the receiver is accidentally left off the hook after the conversation is finished, the line is reported "busy" to all inquirers until the error is eventually discovered and rectified by Central.

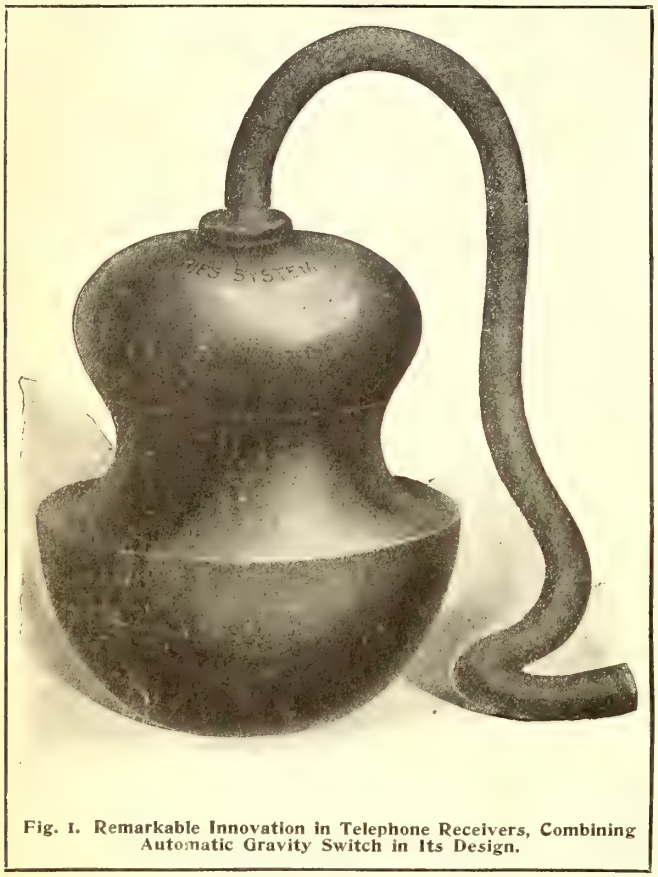

Fig. 1. Remarkable Innovation in Telephone Receivers, Combining Automatic Gravity Switch in Its Design.

In a recently devised automatic gravity switch telephone the hook-switch together with the other complicated features of the present apparatus are entirely done away with. The telephone receiver, which is shown in Fig. 1, has a spheroidical shape and is about the size of a pear. As perceived from Fig. 2, it contains within itself all the requisite switching mechanism. The sectional view clearly illustrates the inner parts of this very unique telephone receiver. A small quantity of mercury or an equally mobile conducting substance is enclosed within a hermetically sealed, conical shaped switching cup made of iron or steel, in which it is free to move under the influence of gravity. When the receiver, which requires no hook support and is, therefore, mechanically independent of the transmitter, is lifted from the normally vertical position (which it assumes when hanging by its cord or when resting on a table) to an approximately horizontal one, assumed when placed to the ear, the mercury immediately changes its position and moves from the lower to the upper portion of the conical cup. In so doing it automatically touches the central disc which is connected to the calling circuit, thus transmitting the calling signal and at the same time establishing electrical connections with the talking circuit. This circuit is made by the mercury and the upper right terminal in Fig. 2.

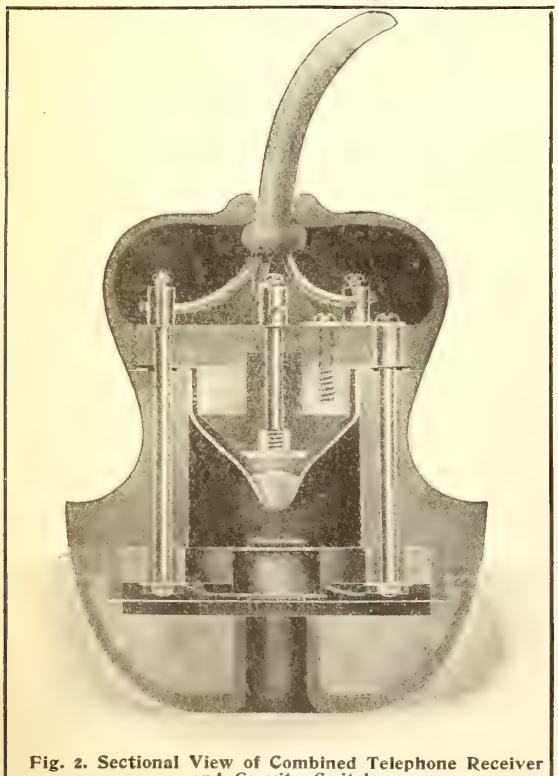

Fig. 2. Sectional View of Combined Telephone Receiver and Gravity Switch.

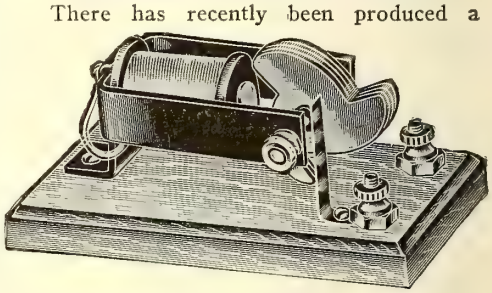
The natural act of putting down or releasing the receiver from the hand after conversation is finished causes the mercury to flow back to the lower end of the cup and in so doing (provided the receiver at the other end of the line has also been set down) automatically operates the "ringing off" or "clearing out" signal at Central, disconnects the talking circuit and restores the subscriber's line to its normal condition ready for another call.

In other words, the natural act of picking up the receiver when one wishes to talk and laying it aside when through causes the automatic and instantaneous action of all the operations which the operator and subscriber have to perform to-day. Thus, for the first time in the history of telephony, there is an elimination of the personal equation of the subscriber from the problem of exchange operation, in which he is now such an important yet at the same time so unreliable a factor.



The regular telephone electromagnet, permanent magnet and diaphragm are located at the lower end of the shell, as perceived, in the cross-section illustration, Fig. 2. In desk telephone outfits the hook is dispensed with and the receiver is automatically kept in a vertical position by the heavy metal cap piece at the lower end of the receiver case. This causes it to resume its normal position when laid down ready for further service. In this instrument only the receiver has to be picked up, as the transmitter need not be handled.

Despite its simplicity, containing as it does but one moving part and that absolutely permanent and indestructible, it performs its manifold duties as above outlined correctly, without regard to the skill of the subscriber or users and with far greater precision and promptness than the most careful and experienced subscriber can command under the present antiquated hook-switch system. With this system a great deal of Central's time is saved by unnecessary questions which the operator begins to ask, such as "Are you waiting?" "Are you through?" etc., etc.

This unique automatic gravity switch telephone was perfected by Elias E. Ries, a well-known consulting electrical engineer of New York City, and his system, fully protected by patents here and abroad, will undoubtedly find favor with telephone companies at an early date it would seem.

A NOVEL MONOCOIL MOTOR.

There has recently been produced a miniature battery motor which can be built for probably less money than any other motor ever designed, considering the power of it. This motor is shown in the accompanying illustration. But one electromagnet is used in its operation and one dry cell will operate this motor at high speed. The current through the electromagnet is made and broken as the armature rotates by means of a circuit-breaker mounted on the shaft, against which a spring brush bears. The principle is well known in dynamo-electric phenomena, but very few motors have ever been built of this type. The motor consumes only .4 of an ampere when operated on a single dry cell. The comparatively heavy armature acts as a flywheel, thus causing the machine to develop a surprising amount of power, considering its size.

Simple Battery Motor Utilizing but One Electromagnet.

HIS ONLY POSSIBILITY.

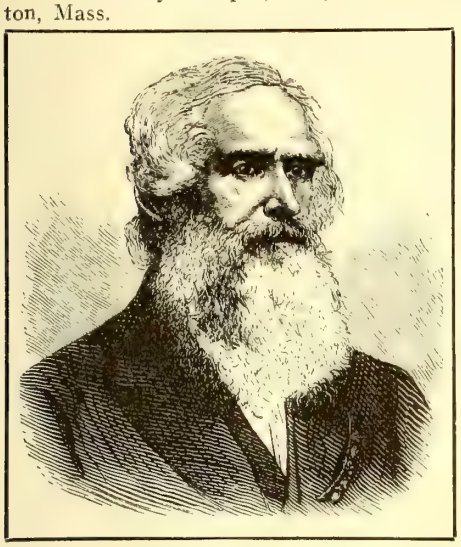
"I believe," said the impatient man, as he put aside the telephone, "that I'll go fishing."

"Didn't know you cared for fishing."

"I don't, ordinarily. But it's the only chance I have of finding myself at the end of a line that isn't busy."

TWENTY-FOUR HOUR CLOCKS.

The 24-hour system of reckoning time was adopted by the telegraph and telephone authorities in Denmark Jan. 1. The system is in use in Sweden, Russia and Norway.



April the Birth-Month of Two Famous Electrical Pioneers

SAMUEL F. B. MORSE.

(Born April 27, 1791—Died April 2, 1872.)

April, 1916, marks his 124th birthday.

Samuel Finley Breese Morse was born on the 27th day of April, 1791, at Charleston, Mass.

Samuel F. B. Morse, Who Developed the First Successful Telegraph.

He started first as an artist, and in order to get better technique studied in Europe twice, during the years 1811-15 and from 1829 to 1832.

During the return voyage from Europe, after his second visit in the year 1832, it happened that he made the acquaintance of Prof. Chas. T. Jackson, of Boston. On the ship he noticed the electrical experiments of the professor, during which the latter made the remark that it should be possible to use electricity as a means of signaling.

After his return from Europe, Morse again devoted all his time to his painting, but he did not seem to make a success of it and was always more or less in financial trouble.

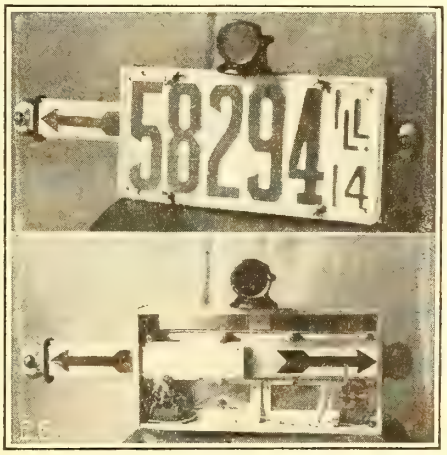
He was the head of the National Academy of Painters, and in the year 1835 received the title of professor. In November of this same year he took up his telegraphic experiments, but inasmuch as he had had very little experience with electricity and as he was not much of a mechanic, he did not obtain any results whatsoever.

In the year 1836 a professor of chemistry, Leonard Gale, gave Morse a great many pointers on electricity, and it was through him that Morse was able to construct his first electro-magnet. As it happened Prof. Gale was afterwards associated with Morse.

Not until the year 1837 were his labors crowned with success and his first apparatus to transmit signals was perfected.

About this time Morse made the acquaintance of Alfred Vail, who supported him financially, and thus Vail also became one of Morse's associates. A good machine was now built and on the 4th of September, 1837, the experiment could finally be called a success, as the first real message was sent over the wires. However, the world did not accept this great invention immediately and at various times Morse endeavored to interest capital in his invention.

O. J. Smith, a member of Congress, gave Morse financial aid and made it possible for him to go to Europe in order to exploit his invention. This, however, proved a failure and he returned to New York in 1839. Morse again resorted to painting in order to make a living. Finally in the year 1843 Congress appropriated $30,000 to put up a large experimental line. This first line, 40 miles long, was erected between Washington and Baltimore and was tested out primarily in May, 1844. Morse's apparatus during this time had undergone a great many changes and very much resembled the present day telegraph instruments.



After this, in an astonishingly short time, Morse's telegraph found its way all over the world. Morse became electrician for the New York and Newfoundland Telegraph Company. In the year 1857 ten of the countries of Europe united in presenting him with a gift of $100,000.

He died in a suburb of Poughkeepsie, N. Y., April 2, 1872, leaving a name long to be remembered among all people.

NEW ELECTRIC AUTO SIGNAL SAFEGUARDS DRIVER AND PUBLIC.

By Lester L. Sargent.

A new electrically operated direction bar or arm for automobiles, invented by Ralph B. Baker, takes the place of a person's arm in indicating which way the car is to turn in rounding corners. The device is combined with the license plate. That is, the license plate is fastened over the box which contains the electric motor and gear wheels which engage two electric bars, one of which is arranged to mesh with a ratchet bar attached to each direction arm. There are two direction arms, one adapted to reach out at either side of the license plate. Arrows are painted on them and they also carry a signal light at the outer end to render them conspicuous at night. The device may be used independently of the license plate, but for reasons of economy and convenience the plate carrier is utilized to contain the electric mechanism that operates the signal arms. The tail light is mounted over the license plate, so as to illuminate both that plate and the direction arms or bars. The small electric motors required for the operation of the device can be operated from the ignition battery of the car.

Open and Closed Views of New Motor-Driven Auto Signal Intended for Rear of Car.

NEW ZEALAND TELEPHONES.

The telephone system of New Zealand is being rapidly developed by the National Government with up-to-date material and appliances, much of which is now coming from the United States.

RAIMOND LOUISE GASTON PLANTÉ.

(Born 1834—Died 1889.)

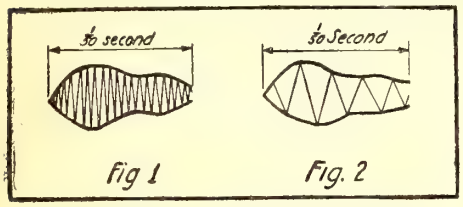
April, 1916, marks his 82d birthday.

The electric storage battery has come into such general use since the advent of

M. Raimond Louise Gaston Plante, Inventor of the Storage Battery.

the automobile, the electric truck and the submarine that it is well to remember that its development was due to Gaston Planté.

It should not be forgotten that the chemical storage battery does not actually store up electricity. When the battery is being charged the flow of current causes a certain chemical action to take place in the battery. When the battery is discharged this process is reversed and the chemical reaction sets up a flow of electricity.



Raimond Louise Gaston Planté was born at Orthez, France, April 22, 1834. He was educated at the Conservatoire des Arts et Metiers in Paris. His profession was that of a chemist, and his principal work was the investigation of the nature of electrical polarization, which finally led to his discovery of the lead accumulator, which bears his name and has given him his fame.

He was always an indefatigable experimenter, and as a result of his experiments on the discharge of cells, he developed a weakness of vision, which greatly handicapped him and which led, in 1862, to his retirement to private life. In 1860 he was appointed to the chair of Professor of Physics of the Polytechnic Association in Paris.

Planté's best-known work is "Recherches sur l'Electricité," issued in 1879, this covering his contributions to the Academy of Science. An immense number of experiments are described in this book, including those which were made with a lead battery of no fewer than 800 elements. It also included a brief description of his rheostatic machine, for which he received the Academy of Sciences prize in 1881. Planté received the diplome d'honneur at the Paris Exposition in 1881 and was also made a Chevalier of the Legion of Honor. It is said that the name of Planté ought to be handed down with those of Volta and Ampère as among the immortal founders of the science of electricity. Renowned for his modesty and amiability, he never troubled about securing patents during the development of his discoveries—although he was fully alive to their possibilities, preferring to let the world benefit by the additional experiments and discoveries of other scientists. He died at Paris, May 5, 1889.

A Writing Machine That Responds to the Voice

WHILE there are many highly ingenious electrical instruments available and in commercial use to-day, including the almost human Telautograph, which will transmit and reproduce ordinary writing, sketches, etc., over an electrical

Demonstrating the Wave Form Characteristic of Letter "B," Uttered Normally at Fig. 1; at a Lower Pitch at Fig. 2.

circuit of considerable length, there is nothing that will more astound the layman than a contrivance so perfectly devised that it will typewrite a message corresponding to any speech delivered vocally to it. In other words, a writing machine that will respond to the voice directly has been the goal striven for by a Brooklyn, N. Y., electrical engineer, John D. Flowers.

Several years ago there were articles published in the technical press about a voice-operated typewriter devised by this inventor and the different letters of the English alphabet were controlled in that case by suitably arranging a number of differently tuned reeds. As the different reeds corresponded to the various characteristics of speech, it becomes evident how this arrangement might work out. This scheme operated fairly well when simple words were clearly spoken in the receiver of the instrument, but it was difficult for this hyper-scientific mechanism to distinguish the consonants.

Much time was spent in experimentation on the failure of the machine to respond to these consonant sounds, but without avail, and finally the inventor concluded that what was required was a much closer study of the minute, and, as we now know, the exact changes and fluctuations of the human voice when uttering any certain sound. For instance, the difference between two speech sounds, such as B and D, was apparently not one of wave frequency. Any change in the number of sound waves would only raise or lower the pitch; however, the characteristic B and D sounds are distinguishable whether or not they are spoken by the highest soprano or lowest basso.

Mr. Flowers went into the study of this subject very exhaustively and, having decided that there were too many complicated side tones and irrelevant tones, such as fundamental and overtones produced by the vocal cords, he arranged an especially sensitive electrical device to pick up and record on a moving strip of film a whispered tone. It has been proven from many exhaustive experiments on a great number of persons of both sexes that these whispered tones in any case will correspond to a certain definite form or pattern for each letter sound of the alphabet. To make this matter clearer, reference is made to Figs. 1 and 2, where the characteristic intensity curve of the "B" sound is shown at 1, while the intensity curve of the "B" sound uttered at a lower pitch is shown at 2. It is observed that in both cases the letter sound pattern is the same and this fact Mr. Flowers succeeded in establishing beyond any question. He has succeeded, with the aid of the apparatus shown at Fig. 3, in producing a complete alphabet of equivalent phonetic, letter sound patterns, as indicated at Fig. 4.

Referring again to the apparatus employed for studying the characteristics of human speech, as shown at Fig. 3, there was utilized an Einthoven galvanometer with silvered quartz fiber which was caused to vibrate by the current generated in a secondary of a step-up induction coil, as illustration indicates. The primary of the induction coil was connected in series with a telephone receiver (used as a check on the test conducted); a controlling resistance of approximately 500 ohms value; a single storage battery cell and an Acousti-

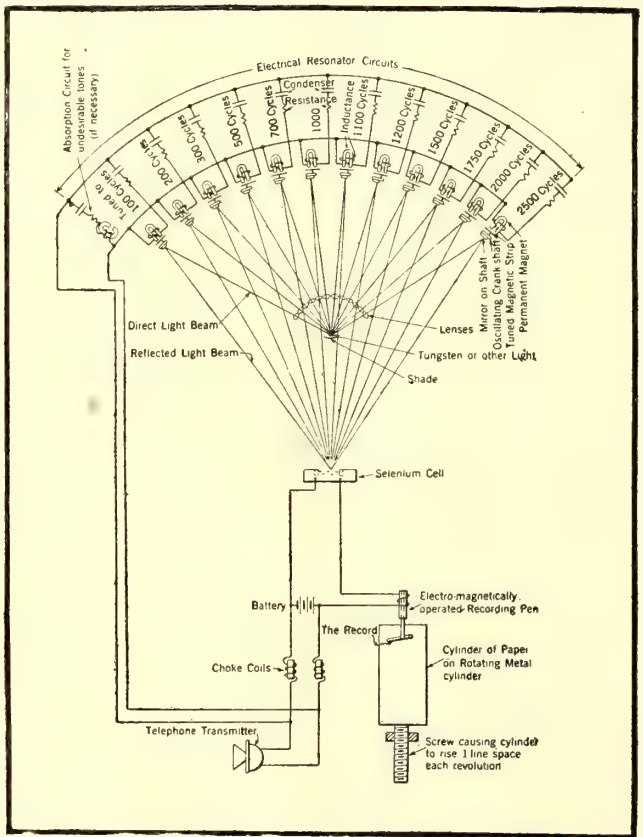


Fig. 5. Arrangement of Electrical Circuits and Allied Devices Used in Writing the Spoken Word Directly.

con microphone or transmitter. As is generally known, this transmitter is used to a great extent in aiding partially deaf people to hear better, and it is so remarkably sensitive to sound waves that *whispers* have the same effect as would the ordinary tone of voice on the standard microphone supplied with the common Bell instruments.

An arc lamp was used to give a strong beam of light, which was intensified through a series of lenses, with the result that the slightest motion of the galvanometer string was magnified 900 times when it reached the recording film in the camera observed at the right of Fig. 3. The galvanometer string consisted of a fine silver-plated quartz fiber .0001 of an inch thick, supported between the two poles of a very powerful electro-magnet. The ray from the arc lamp was focused upon this quartz fiber through a hole in the magnet poles, and by means of a second system of lenses the image of the string was photographed as a spot on the rotating drum of the camera. Whenever a sound was whispered in the proximity of the Acousticon microphone the latter varied the current of the primary and conjointly the secondary current of the induction coil and which effect was manifested in the galvanometer by the string vibrating more or less in accordance with the strength of the sound and its particular letter characteristic.

When the shadow of the galvanometer string moved back and forth about two inches the electrically operated camera shutter was opened for one revolution of the wheel and a five-foot photographic record of the word whispered was thus obtained. While many speeds, even as high as one mile per minute, were tried, the rate of 1,080 feet was found suitable for most of the work. The light from the arc was interrupted 500 times per second, and in this way vertical lines were automatically photographed on the moving film at intervals of two-thousandths of a second, by virtue of a specially constructed time wheel.

Mr. Flowers, in speaking of his work in this direction, states that speech patterns so photographed on the moving film and of the same identical sound are practically exactly alike for all persons and independent of their age or sex. In this fashion 500 different records were obtained of three men's speech and one woman's to substantiate the arguments here set forth. This work was conducted by the co-operation of the Department of Physiology, College of Physicians and Surgeons, New York, and the Underwood Typewriter Co., so that unequaled facilities were at hand in this most remarkable study of the human voice and its fluctuations.

In the present instance the investigator decided that, knowing exactly the particular curve corresponding to each letter of the alphabet, when uttered by any person regardless of age or sex, he would do very well to perfect or design a machine which would trace out exactly these differ-

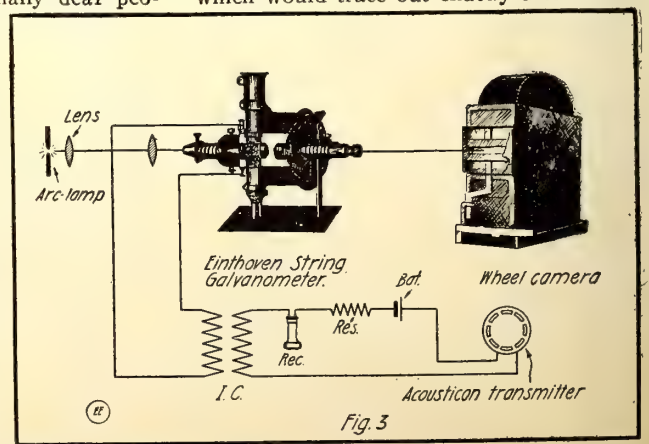

Fig. 3. Using an Einthoven String Galvanometer and Special Camera to Photograph Whispered Speech.

ent curves if *anyone should speak to it.* Accordingly, he has evolved a scheme as perceived at Fig. 5. This machine, it should be said at the start, utilizes a stylus or pen which writes or traces out the curves as shown in the phonetic alphabet at Fig. 4, corresponding to each letter of the English alphabet. Hence, if this was to be used commercially or otherwise, it would be necessary for those making use of such a "phonoscribe" (if we may so term this device), to learn this alphabet or else to employ a transcriber who could read it. Needless to say, it could be easily memorized, just as the notes of a musical composition are or the characteristic sounds of the letters employed in the study of foreign languages.

The voice-controlled phonetic typewriter as here outlined makes use of a selenium cell, which cell has a blank space at the center of its face. Ordinarily the beam of light caused to strike this cell rests on this blank spot. In operation a person speaks into the telephone transmitter or microphone and any current undulations thus set up in its circuit are prevented from reaching the stylus mechanism by the choke coils inserted between the batteries and microphone. Hence the current variations produced by the microphone, when spoken into, will proceed to the series of tuned circuits employing different values of inductances and capacity and arranged in the segment of a circle, as observed. These tuned circuits include a specially tuned resonator of the magnetic type. This comprises a pair of electromagnets in front of which is mounted a tuned magnetic strip, as indicated at Fig. 6. This resonator, which is tuned for any one tone of speech at any instant will therefore respond, likewise the current existing in it at any moment will vary in strength according to the speech variations at the microphone. Thus when the proper resonator responds to the corresponding letter sound the magnetic strip will vibrate powerfully, which will cause the connecting rod shown in Fig. 6 to oscillate the delicate shaft there shown. The connecting rod is secured to the shaft only .004 of an inch from the center line of same. It is thus possible to create an angular motion of the shaft of 1½ degrees when the magnetic strip has a given motion of but .0001 of an inch. Furthermore, a mirror attached to the shaft will move or oscillate with it, causing a beam of light from a tungsten or arc lamp (as indicated in Fig. 5, and passed through a series of

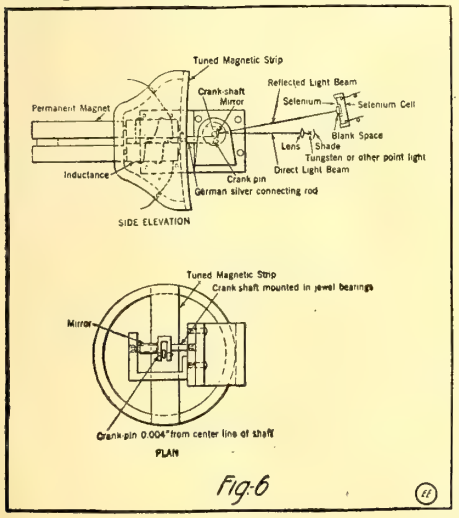

Fig. 6. Details of Tuned Magnetic Resonator and Reflecting Mirror.

lenses) to be reflected on the selenium cell aforementioned.

As stated, normally the spot of light rests at the center or on the blank space on the face of the selenium cell. When the reflected beam of light begins to oscillate it swings back and forth past this central dividing space and both halves of the cell are lighted proportionately to the amount of current energizing the electromagnetic resonator. When this occurs the selenium cell lowers its resistance in the well-known manner, and in turn this varies the amount of current passing through the electro magnetic solenoid, controlling the stylus which *traces the phonetic alphabet curves* on a revolving cylinder or drum. It may not seem possible that such a machine as this would write down or copy ordinary words, but such is the case, according to researches conducted by the inventor. This is so, he claims, because in uttering a *word* the sounds corresponding to the letters in the make-up occur consecutively, the recording pen of the "phonoscribe" thus writing out in a continuous line the connected sounds, as it were, of each letter in the word.

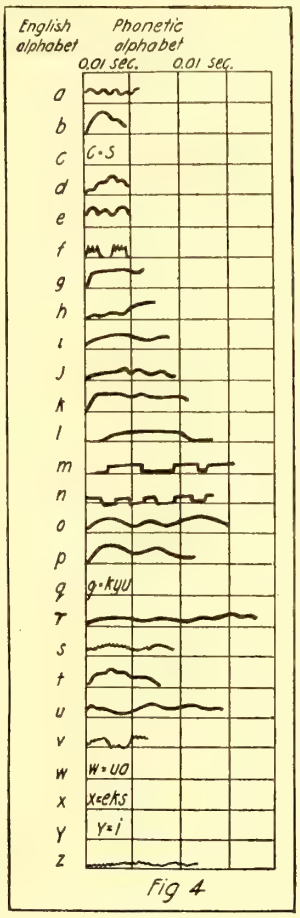

Fig. 4. The New Phonetic Alphabet Evolved by Mr. Flowers.

NEW USES FOR TELEPHONES.

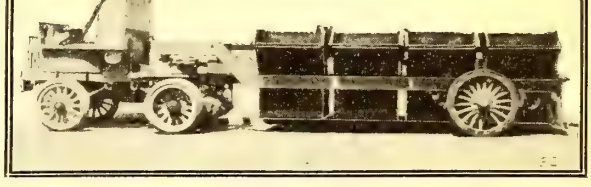
Further experimentation on the loud-speaking telephone for railway train dispatching work has resulted in a loud speaker that is an unusual combination of distinct enunciation and large volume. A number of these instruments have been installed during the year on many of the lines of important railroad systems, where they are doing efficient work.

A new type of hand telephone has been developed in collaboration with the United States Forest Service for use in forest service patrol work. This hand set is a complete local battery telephone set which weighs only 2¾ pounds, making it the lightest satisfactory portable local battery set obtainable. The omission of a hand generator makes this possible.

Signaling of other stations on the line is done with an interrupter mechanism which operates a howler, connected at the permanent station, in addition to the regular bell of the stationary telephone. It is possible with this equipment to send a howl over a longer line. The hand set consists of a transmitter, receiver, induction coil, battery, signaling interrupter and talking and signaling push buttons.

GASOLINE-ELECTRIC TRACTORS HELP CLEAN NEW YORK CITY STREETS.

For some time past the New York Street Cleaning Department has been trying out various tractor and trailer combinations for the collection of ashes, garbage and street sweepings, as well as for mechanical sweeping and flushing of streets. The experience gained in this experimental work showed that while the electric tractor was highly desirable from the standpoint of operating simplicity the mileage limitation imposed by the storage battery equipment was a handicap. Further, that because of the many stops in collection work (60 to 100 per hour) the gasoline tractor with gear transmission clutch, spark and throttle control was not only impractical, but presented the disadvantage of greater complication, with the resulting necessity for a higher class of drivers.



It has long been appreciated that the real work of street cleaning and flushing must be done at night, and the collection of refuse during the day. This calls for at least 16 hours service in 24.

A type of tractor which would be capable of practically continuous operation and adaptable to either kind of service was evidently necessary. A tractor equipped with a gasoline engine driving an electric generator, whose output could be used in motors driving the rear wheels, was accordingly chosen as having the simplicity of control of an electric vehicle and the relatively large mileage capacity of "straight" gasoline equipment. This combination also presented the advantage of providing in the most convenient form energy for driving the auxiliary apparatus used in street sweeping and flushing.

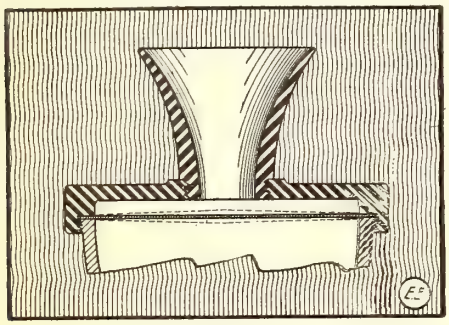
Twelve such tractors are now in use by the Department of Street Cleaning in this city.

The electric motors are suspended by links from extensions of the rear spring hangers and by extensions of their cases which bear on the rear axle. The motors drive by spur gears to intermediate shafts, which carry pinions engaging with internal ring gears mounted on the rear wheels. The use of pressed fabric pinions on the motor shafts has resulted in extremely quiet operation. The motors themselves are, except for the special cases, of the standard automobile type with ball bearings.

A 40-horsepower gasoline engine was thought to be a proper selection. The engine used in the tractors is a four-cylinder type. A centrifugal governor maintains a rotative speed of 900 r. p. m., this latter being the rated speed of the electric generator.

Gasoline Electric Tractors Clean New York City Streets.

The generator is rated at 15 kilowatts, 125 volts, 120 amperes at 900 r. p. m. The electric wiring is all carried in metal conduit, and the controller, cut-out switch and ignition switch are placed in a sheet-steel box beneath the driver's seat.



In Zurich, Switzerland, street cars are run by liquid air.

How to Talk Into the Telephone

By Robert W. Phelps

"HELLO! Hello! Hello; can't hear you. Talk louder, please!"

How often do you say this when you cannot understand the party on the other end of the telephone? The party on the other end of the line raises his voice and yet the voice sounds as if from afar.

This diagram of the mouthpiece of a telephone transmitter illustrates how the diaphragm vibrates. The greater the intensity of the voice the greater the intensity of vibrations of the diaphragm and the electric impulses sent over the wires.

You shake up the telephone transmitter and he does the same. Sometimes this obviates the trouble and sometimes it does not.

Possibly you frequently converse with a party with whom you invariably experience difficulty in hearing his voice plainly through the 'phone. You know that this party usually talks directly into the mouthpiece of the transmitter so loud that he can be heard for several rooms about, and yet his voice sounds very faint at your end of the telephone.

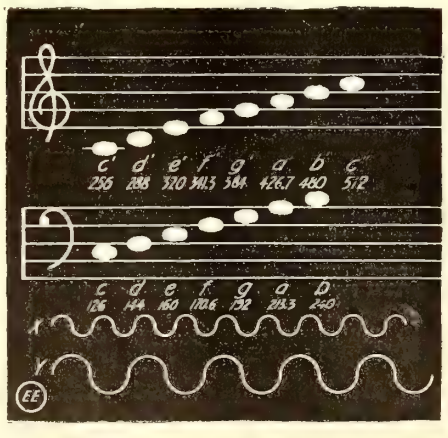
Possibly you also talk with another party who sends every word through the telephone as clear as if he were speaking directly into your ear. And, further, you have seen him using a telephone, speaking in a low tone that was hardly audible 10 feet away. Why is one party so plainly heard, speaking with but little effort, and the other with so much difficulty?

A little knowledge of sound and its application in telephoning will save much annoyance in telephone conversation, as well as do away with much unjust condemnation of telephone companies for poor service.

Sound is the impression produced on the ear by the vibrations of an elastic medium, such as air. Such vibrations radiating from a source are spoken of as *sound waves*. Sound waves travel in air at the rate of about 1,100 feet per second. The length of the wave determines the pitch of the sound. That is, the greater the number of waves striking the ear per second, the higher the pitch. The height, or amplitude, of the wave determines the intensity or loudness of the sound. At the point at which the sound originates the intensity is the greatest, and its intensity decreases as the wave travels. The velocity remains the same from the time the wave starts until the intensity becomes nil.

Each note on the musical scale has a definite number of vibrations per second. As an example, middle c, designated as c′ in the accompanying musical scales, has 256 vibrations per second. The note one octave higher, designated as c″, has 512, just twice as many as middle c. The note c, one octave lower than middle c, has but 126 vibrations per second, or one-half the number of middle c.

In general the number of vibrations per second are doubled when the pitch of sound is raised one octave.



Ordinarily the higher the pitch of sound, the less the amplitude of the wave. When the higher notes have the same intensity as the lower notes they become shrill and unpleasant to the ear. It will be noticed that when a soprano singer reaches for the higher notes, the tone is more pleasing to the ear when not sung loudly. How different with the basso.

Now let us glance at the diagram illustrating the propagation of two sound waves for the same length of time, but one having a pitch of one octave higher than the other. In the same length of time the higher pitch has twice the number of vibrations as the lower. In tones of the same quality the intensity of the waves X is about one-half that of waves Y.

When these waves strike the diaphragm of the telephone transmitter the higher pitch causes the diaphragm to vibrate with twice the rapidity of the one an octave lower in pitch. The higher pitch does not cause it to vibrate with the intensity of the lower pitch, for two reasons. The first is, that the wave of the higher pitch does not have the amplitude of the wave of the lower pitch. The second reason, which is probably the more important, is that each vibration of equal intensity of the diaphragm absorbs about the same amount of energy. Therefore the diaphragm absorbs twice the energy to overcome its inertia, when vibrating in the higher octave, than it does when vibrating in the lower octave.

It should be kept in mind that there are two diaphragms in a telephone instrument —one in the transmitter and one in the receiver.

With the above knowledge of the rudiments of sound and its application to the use of the telephone, the natural conclusion is that the lower the pitch of the voice at the transmitter the more audible will it be at the receiver of the telephone. When not understood over the 'phone, one should, therefore, lower the voice, rather than allow it to rise to a higher pitch. Try it the next time you use a telephone and watch the results.

Every note on the musical scale has a definite number of vibrations per second, as indicated above. It makes no difference how loud or how soft middle "c" is sung, it always has 256 vibrations per second. Each octave difference in pitch, going up the scale, doubles the number of vibrations per second.

The two lower curved lines represent sound waves having a difference of one octave in pitch, but of the same quality. The upper wave is the higher pitch.

YOU CAN PHONE THE CHEF NOW

"Hello! Give me one 602, a little 312, two 874 and a cup of 302."

No, these are not the signals of a football quarterback; they are simply the indications of a fairly good appetite as expressed over the special restaurant telephone system installed by the Ritz Co., which runs a lunch room in Plainfield, N. J. Instead of using waiters to take patrons' orders, the company has equipped its restaurant with telephones. One of them *waits* patiently at every table. The

"'Phone the Chef," the latest fad in restaurant novelties.

lines from these tables are connected with the kitchen.

The operation of the system is simple. When the patron takes his seat at the table he studies a menu whose dishes are indicated by numbers. When he has made his selection he picks up his telephone and gives his symbolic order to the chef.

"PAUL REVERE" VIA RADIO.

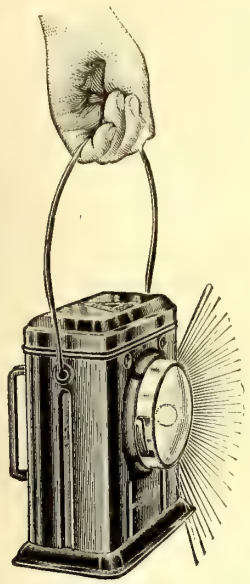
The preparedness and skill of the 25,,000 licensed amateur wireless operators of the United States was tested by Uncle Sam on Feb. 21, when a message appropriate to the celebration of Washington's Birthday was sent to William H. Kirkwin at the licensed station "9XE" for transmission throughout the country. The message, which was dispatched at 11 o'clock, was picked up by all stations within 300 miles of Davenport and relayed in every direction for transmission to the governors of each State and the mayors of the principal cities. The message read as follows:

"A democracy requires that a people who govern and educate themselves should be so armed and disciplined that they can protect themselves.

"COL. NICHOLSON, U. S. A."

The message was read by boy scouts at Mount Vernon and at Bunker Hill.

The wireless message urging preparedness was duly received in Washington and delivered to the policeman who stood on guard at the White House office at 2 o'clock in the morning. He delivered the message to Secretary Tumulty for presentation to the President.



On account of the number of relays, it required about an hour and a half to send the message from Davenport to the Pacific Coast, more than 2,000 miles from its starting point.

The message was characterized by some of those interested as "Paul Revere's ride done into wireless," as with the changing of the words it might have been utilized to call a nation to arms, much as Paul Revere called the Minute Men.

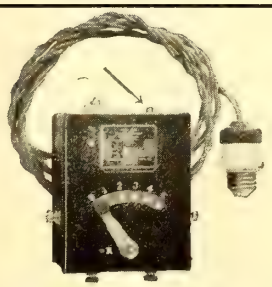
A surgeon in the Japanese army is reported to have invented a machine run by electricity that grinds as many beans into flour in 40 minutes as a man can grind by hand in a day.

NEW TWO-CELL ELECTRIC LANTERN.

A very practical and useful design of an electric lantern has recently been developed by an enterprising concern; it is designed to accommodate two standard dry cells instead of one. This of course gives much

New Electric Lantern Uses Two Standard Dry Cells.

greater life to the lamp for a given candlepower, and also a larger bulb than that adapted to the single-cell style of lantern may be used.



The case is made from a steel shell which acts as a container for the batteries, and the bulb supplied with it is of the tungsten type with an efficiency of about 1 watt per candlepower. The lamp is fitted with a 3¼-inch silver-plated reflector, designed to throw a well-diffused light over an arc of 180 degrees, but especially concentrated beam reflectors can be furnished if desired by the purchaser.

A powerful concave-convex lens 3¼ inches in diameter is fitted in front of the reflector and tungsten lamp.

The case is neatly finished in baked black enamel with trimmings of polished nickel. The manufacturers of this latest type electric lantern for the utilization of dry cells claim that it gives steady service and it sells for a very nominal price commensurate with the high quality of the workmanship and materials involved in its construction.

NEW TOY TRANSFORMER HAS CIRCUIT BREAKER ON IT.

A progressive manufacturer of toy step-down transformers suitable for reducing 110-volt, alternating current lighting cur-

This Toy Transformer Has a Circuit Breaker on It.

rent for running toy railways, etc., has at last developed an important detail on this much-used device, which promises to be a boon to those making use of such apparatus. This improvement is in the form of an automatic circuit breaker which opens the primary circuit of the transformer; i. e., it disconnects the 110-volt current whenever the secondary of the transformer is overloaded, such as by a short-circuited section of toy railway track, etc. The circuit breaker will continue to trip open, no matter how often it is reset, so long as the short-circuit exists across the secondary of the transformer. The illustration herewith shows the appearance of this attachment and the transformer complete. The circuit breaker is reset by means of a small push button, to which the arrow points. The secondary is adjustable for different voltages by means of a switch, as observed, and undoubtedly this innovation will be highly appreciated by those having to make use of this important piece of apparatus, which is much in demand for operating small battery motors, toy railways, low-voltage lamps and other miscellaneous toys and devices.

BATTLE CREEK, MICH., HIGH SCHOOL WIRELESS CLUB.

The High School Wireless Club resumed activities with the opening of school in entirely new quarters. The operating room has been moved from the physics laboratory in the basement to the observation dome at the top of the building, and the work of reinstalling the instruments and wiring recently completed makes this one of the best sets in the State.

Forest Phippany, Dale Ball and other members of the club at the high school building for some time preparatory to the change, and they now have things in shape for a busy season.

The European war and recent ocean disasters have aroused a keen interest in the wireless telegraph and there are a dozen stations in Battle Creek now. A number of the members of the high school club have stations at their homes. The high school station and many of the others here catch messages from Arlington, Va., and other far-away points, and have a sending radius of from 100 to 200 miles.

With the wireless room in the dome of the building, away from the noise and confusion from the streets and corridors, it is thought that the efficiency and range of the station will be greatly increased. A number of new parts have been installed and the old sending and receiving apparatus, which is standard in every particular, has been completely overhauled.

AN ELECTRIC FOUNTAIN.

It is often desirable to complete the decoration of a room or restaurant in an attractive manner by utilizing a small fountain, but until quite recently this was impossible on account of the numerous pipes necessary to conduct the water supply to and away from the fountain.

The only natural solution of this problem lies in using the same water over and over. To accomplish this end the fountain here illustrated has been brought out.

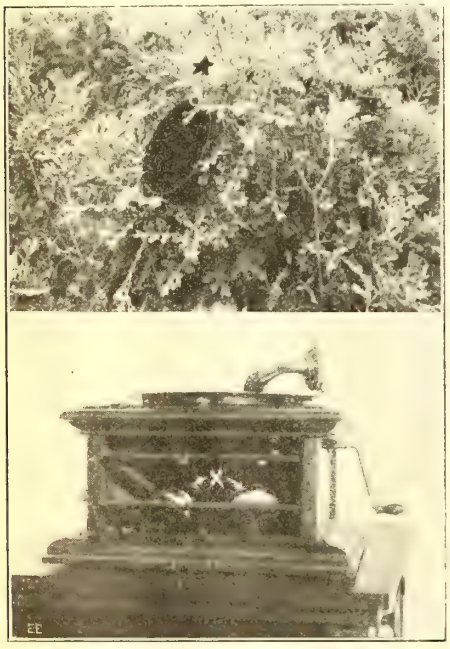
This beautiful display may be placed in any position, anywhere, and requires nothing but a cord connection to the nearest electric light socket in order to continue its action indefinitely, or as long as the current is turned on.

The base of the apparatus contains a motor-driven pump which forces the water up through the several jets surrounding the figure, as observed. The water then falls back into the large basin around the

Electric Fountains Are Now Available in All Sizes for Parlor or Dining Room Decorations.

foot of the figure and flows to the pump again, only to continue the same cycle. The water is prevented from splashing by means of this large basin, specially designed.

The design here pictured measures 24 inches from the top of the figure to the base, which is 15 by 12 inches. The jets of water reach a height of 30 inches, which is sufficiently high for use in a conservatory or a large room when the fountain is placed on the floor.



The motor operates on either an alternating or direct current circuit. The current consumed is very small; the actual cost of operating the fountain is about 1 cent per hour. The apparatus will last indefinitely and should prove a real asset around country homes or hotels. There is nothing more beautiful or ornate than a water fountain for interior decorations, dinner spreads, balls, parties.

A MUSICAL GARDEN WALL.

By Albert Marple.

A loud-talking telephone is one of the most recent electrical inventions of Earl C. Hanson, the 22-year-old inventor of sunny Los Angeles. The function of this loud-talking device is to take the sound of the human voice or the music from a phonograph or other instrument and multiply it as many times as desired. This effect is secured by means of an amplifier, which after several years of hard work has been highly perfected by this young inventor. The extent to which the sound may be multiplied is governed only by the amount of electrical energy employed.

The work of this instrument may be more definitely understood if the description of a recent test is given. Incidentally, it may be stated that this instrument has been given a number of try-outs recently in and around the city of Los Angeles, and wherever the wonders of the device have been heard the instrument has proven a sensation. The principal demonstration was held at the country home of one of the most prominent judges in southern California. On this occasion the "central station" was the music room in the beautiful

Above: Loud Talking Telephone Placed in Garden Shrubbery. Below: Cross Indicates Amplifier Microphones Placed in Phonograph.

dwelling, and the receiving stations were located at various points throughout the grounds surrounding the home. The moment the phonograph in the music room was started the gardens, several hundred acres in extent, were filled with sweet melodies, grand opera arias, popular selections and instrumental pieces, following one another in rapid succession.

Over all parts of the garden the music could be heard just as distinctly as could the phonograph at the central station. In the garden this music seemed to come from a beautiful border hedge, at another point it seemed to drift from a mammoth rose vine, while at another point the music waves seemed to come from the wide-spreading branches of a beautiful pepper tree. The telephonic receiving stations were hidden from the view of those in the garden, and to each receiver was attached a small megaphone. As the ranges of sound from the various receiving stations overlapped it seemed for all the world as though the very universe was filled with music.

It is not claimed by Mr. Hanson that this is the first time that phonograph music has been transmitted over the telephone, but he does declare that he has invented an amplifier which will increase any volume of sound many times.

The inventor believes that the field in which this new device could most profitably be used, in his opinion, is in connection with park concerts given by the municipality. For this work a "central station" could be located near the center of the city, with receiving stations at each of the public parks within the municipality's borders. At any given time during the day or evening a concert of phonograph selections played at the "central station" could be reproduced simultaneously at all of the parks within the system or circuit, the only expense to the municipality being for the employe who operates the phonograph.

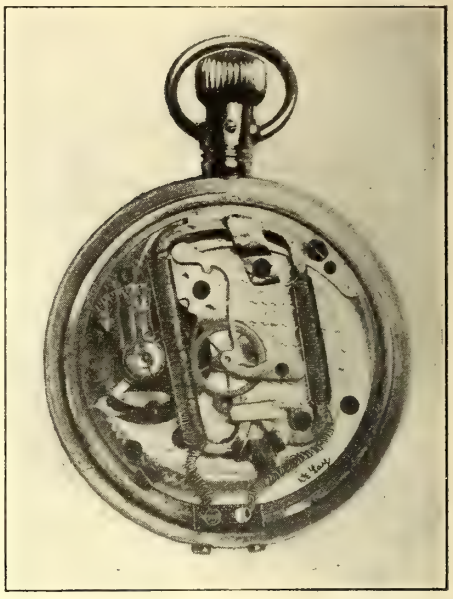
With the exception of the amplifier there is nothing complicated about this "loud-talking" system. It is of ordinary telephonic construction. The music from the phonograph is played into one or more regular telephone transmitters. From these transmitters (marked X in photograph) it is carried by wire to the amplifier, which intensifies it as greatly as desired. From this instrument the sound, greatly augmented in volume, is carried over a double wire to the various receiving stations.

There is another feature about this apparatus or system which is of interest. When operated from the receiver to the transmitter ends it has the effect of a "dictagraph." While for those sentimentally inclined music in cozy corners and nooks is admirable, a disadvantage with the machine is that it would be dangerous for lovers to whisper "sweet nothings" nonchalantly, for the slightest sound is carried back to the "central station," where it is amplified and may be distinctly heard by the operator.

WIRELESS KILLS WOMAN.

Wires from an amateur radio telegraph apparatus sagging down and coming in contact with a live wire of an electric light plant recently killed Mary Roskinsky, a servant, employed in the family of Chas. Abrams, living at 518 Fourth avenue, Astoria, L. I. The wireless apparatus belonged to Mr. Abrams's son, Herbert Abrams, 18 years old.

He had an apparatus run by dry batteries set up on a small table in his bedroom in the rear of the second floor. The victim's right hand grasped the key of the instrument while her left hand clutched one of the wires which had been grounded on the steam radiator within one or two feet of the table.



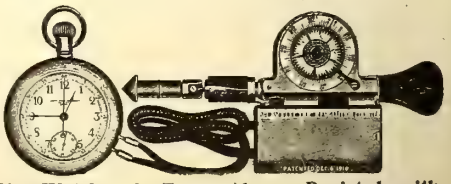
The police found that the boy, in equipping his plant, had run his aerials out of the back window of his bedroom from the rear of his house for a distance of about 100 feet. During a recent storm the wires were weighted down by snow and became slack, so that in a light wind they occasionally knocked against a primary wire of the New York & Queens Electric Light Co. which was carrying 2,400 volts. Just why the girl caught hold of the key of the wireless apparatus is not known, but it is thought she probably started in to clean around the table and was in the act of moving it when the aerial wire sagged down and came in contact with the heavy feed wire below. In the shock she suffered the table upset and she was killed.

AUTOMATIC 'PHONE USED IN NORWAY.

The Norwegian Government is planning for an automatic telephone exchange in Christiania, and the first of the kind in Norway.

SPEED COUNTER AND STOP-WATCH ELECTRICALLY CONTROLLED.

An extremely useful device in the line of stop-watches and speed counters, which are widely used by engineers, machinists and others, is incorporated in the electrically



Electro-Magnets Accurately Control This Stop-Watch.

manipulated stop-watch perfected by Frederick A. De Lay.

The illustration herewith shows the interior mechanism of this electrically operated stop-watch. A small electro-magnet is mounted on the regular movement of same, as perceived. It is so arranged that the sweep hand engages when the circuit is open and becomes disengaged when the circuit is closed. This particular arrangement and refinement permits of very accurate timing of any operation in which the starting and stopping action can be made to open and close the circuit of the electro-magnet.

When this unique electric stop-watch is used with a revolution counter they are interconnected electrically, so that as the counter dial starts to turn the electrical circuit hooked up to the stop-watch is automatically opened and thus permitted to start same. The watch and counter automatically stop at the same time, since stopping the counter's shaft again closes the electro-magnet's circuit, which includes a small flashlight battery contained in the metal case attached to the counter. It is understood that the electro-magnetic attachment here devised does not interfere in any way with the use of the watch as a time-keeper or as a manually operated stop-watch.

The cost of this outfit is quite nominal

Stop-Watch of Type Above Depicted with Speed Counter and Electric Circuit Controller for Same.

and it should appeal to electricians, machinists, inspectors and others who have to do with the testing of any machinery, and, besides, there are many diversified applications to which this ingenious and accurate timing arrangement can be adapted, as, for instance, the timing of horse and foot races, train velocities, et cetera.

Timing Your Telephone Speech

By Frank C. Perkins

The accompanying illustration shows the use of a novel form of meter recently developed for timing long distance and toll telephone calls. It is pointed out that time and money are lost because of inadequate means of checking toll calls. An instance is given below:

A Philadelphia genius called at the office

Unique "Minute Timer" for Telephone Users. Especially Valuable on Long-Distance Calls.

of a business friend and found him engaged in a long-distance conversation with a factory manager. The business man rang off and turning to his visitor, said:

"Three minutes is not time enough for a long-distance call. I must concentrate my message into a very few words or else pay for excess time."

A few minutes later a salesman in Boston was on the wire. The visitor timed the conversation. It consumed a minute and a quarter. This business man, therefore, paid for six minutes of service, but used less than three minutes. This occasioned an actual loss of $2.50.

A careful investigation has conclusively proven that only about 46 per cent. of the time paid for is actually used. The balance is pure waste, which means a real monetary loss to American business—amounting, in fact, to more than $60,000,000 a year.

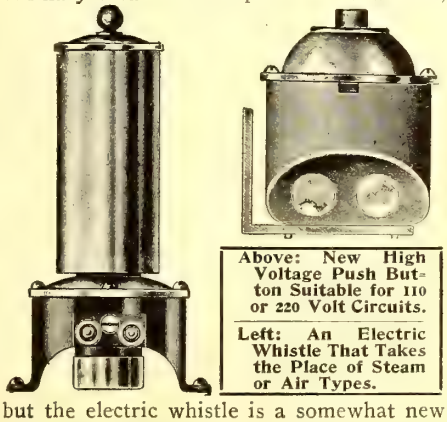
Whether one uses the long-distance service much or little, there is this waste. It is one of the few leaks in modern business that has not been checked. It became evident that there was a real need for a simple, yet effective, device for timing long-distance calls and increasing the telephone efficiency of business men.

The "phone-meter," here illustrated, is a neat little clocklike device, with a single hand and a specially designed dial. It is so simple and inexpensive that at first glance one can scarcely perhaps appreciate its great utility.

It will be seen that the "phone-meter" is a check on the person using the 'phone, rather than on the telephone company—yet it does both. It enables one to use all the time paid for, and one can more readily concentrate the mind on the message, instead of thinking about possible excess charges. It enables one to talk more leisurely and often do a little "visiting" over the wire after finishing a business message.

This instrument is also a check on interruptions, as it enables one to stop the time until the connection is restored. If the operator knows that one has a "phone-meter" she will not charge for the loss of time resulting from broken connections. The lost time on two or three calls often amounts to more than the price of the instrument.

WORLD-WIDE RADIO 'PHONE.



Wireless telephony will soon extend around the world, Secretary of the Navy Daniels told guests at a banquet given at the Lotos Club recently in honor of John J. Carty, who has succeeded in extending the uses of the wireless telephone.

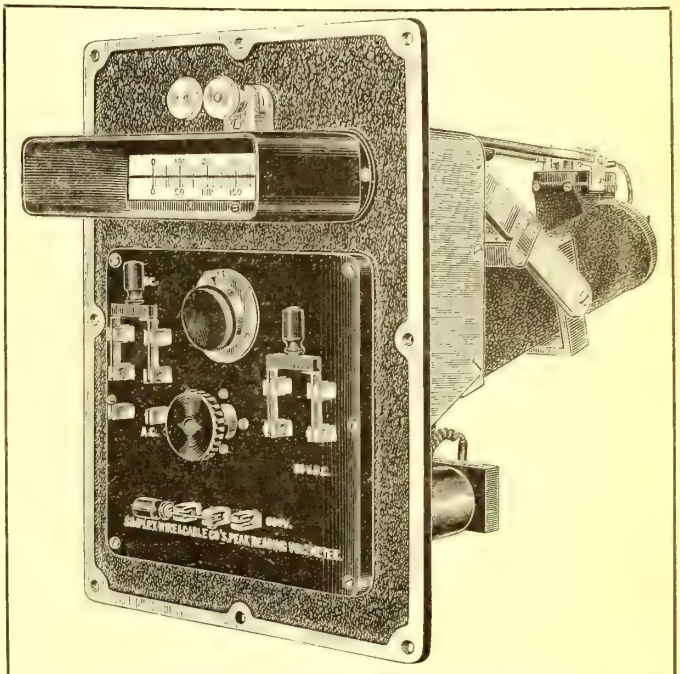
"We thought until recently that wireless telegraphy was the last of modern miracles that had to do with communication," said Secretary Daniels. "Recently the world was amazed when from Washington, without wires, the human voice was heard in San Francisco. When fully perfected, we may talk to our friends 'from Greenland's icy mountains to India's coral strands.' The man whose genius is making this miracle possible is Mr. Carty."

At the banquet table were telephones connecting with the wireless stations at San Francisco and elsewhere.

NEW ELECTRIC WHISTLE AND HIGH VOLTAGE PUSH BUTTON.

Most every one has heard and seen the ordinary steam or compressed air whistle,

Above: New High Voltage Push Button Suitable for 110 or 220 Volt Circuits.



Left: An Electric Whistle That Takes the Place of Steam or Air Types.

but the electric whistle is a somewhat new device, so it seems. The illustration herewith shows one of these perfected devices, which operates on either 110 volt or 220 volt a.c. circuit, or from a 10-volt battery circuit. These whistles operate on the principle of a vibrating diaphragm.

To control such devices as this is naturally beyond the province of the ordinary push buttons used for bell circuits and the like, so a special type of high voltage push button, shown in the second illustration, was perfected. This button is practically the same size as the ordinary bell push. In the illustration it is shown fitted onto a special conduit box designed for use with it. These buttons may be used for operating 110 or 220 volt circuits controlling horns, bells, lights, elevator systems, motor control circuits, etc.

A PEAK READING VOLTMETER.

One of the leading American manufacturers of electrical measuring instruments has recently brought forth what is termed "a peak reading voltmeter." This instrument has been in great demand in the past and will undoubtedly find considerable adoption in the future. This meter affords a practical means for determining the *maximum voltage* on any alternating current system, reading the potential direct and always independent of the form of the wave, besides indicating the maximum voltage at all times.

A "Peak" Reading Voltmeter That Registers the Maximum Voltage of Alternating Current, Besides Indicating Variations in These Values.

As the meter also shows variations of the maximum voltage, it serves as an indicator of distortion of the wave form. It was particularly developed for use in connection with high tension cable testing, where, due to the capacity load, distortion of the wave is very likely to occur. It is, however, applicable to any alternating current apparatus or system, where a quick and accurate knowledge of the maximum voltage value is required.

In contradistinction to the ordinary voltmeter, this instrument reads the highest voltage attained by any wave of commercial frequency, while the instruments generally used for measuring alternating current potentials indicate the *effective value* which, of course, is about 30 per cent. less than the maximum or peak voltage of the current passing through the circuit. The common 110-volt a.c. lighting circuit, for example, has a maximum peak potential of about 155 volts.

The "Live Wire"

By Adelbert H. Wolfe

Read This Article on the Live Wire. It Explains How the Current Traverses a Conductor by Electronic Vibration

THE term live wire is often mentioned in speaking of high potential circuits.

There seems to be a mysterious phenomena surrounding it which impresses one of its importance. It is always considered as something dangerous to come in contact with, as it will severely burn, and if the amperage is sufficiently high will cause death to animal life. Let us consider this wire that possesses these dangerous and death-dealing qualities, and which will, if more current is added, melt, consume itself, and go up in smoke. The question is, how does this wire differ from any other wire lying around? Of course, you would readily answer that the above mentioned live wire is connected into a circuit, which is supplied with sufficient amperage and voltage to bring it to that high temperature in which it turns to molten metal.

Let us endeavor to learn more about this mysterious phenomena by taking for an example a battery, key and sufficient wire to complete the circuit, Fig. 1.

When the key K is depressed we know that current flows from the positive plate of the battery A, through B and down to the key K, passing through its points and back to the negative plate C of the battery. It was mentioned that current flowed from the positive to the negative plate in the external circuit, as that is the theory most generally used. But the writer feels safe to say that current not only flows from positive to negative in the external circuit, but also vice versa, or from negative to positive. The writer will take this up further in another part of this article.

Before we go any further let us refer again to Fig. 1 and answer a couple of questions.

1st. What is the condition of the open circuit before the key is depressed?

2d. What is the condition of the closed circuit after the key is depressed?

The above questions we will have to answer before we can determine what there is in the wire to make it heat.

In taking up question 1 let us first get at the bottom of the phenomena of electricity flowing through a wire. We know in the first place that everything material consists of molecules and atoms. The writer would like to make this article as simple as possible and deal only with molecules, but in dealing with current flow there is something else which we must take into consideration, and that is the electron. This very tiny germ of physical force is comparatively at home among the atoms and molecules of all metals and most liquids. It can easily penetrate a molecule and pass around through its atomic structure, tearing off a piece of an atom here and there. These tiny agents, the electrons, have the whole responsibility of transmitting the electric charges in a wire to their destination so far as we know. They are the electric charges themselves, and without them we would not have any electric current. They are the seat of current flow, that is, a positive particle is repelled by its positive neighbor and attracted by its negative one.

In case of question 1. When A B is connected to positive plate A and the circuit is open at K we need not think for an instant that the positive charges in the plate A of the battery remain there. No, as quick as contact is made, they rush out through the new road of molecules and atoms seeking a way of escape, only to come at rest when the whole portion of the circuit from A to K is occupied.

Referring to Fig. 2 we have shown a portion of the circuit on a large scale; K represents the key points, C and A the negative and positive sides of the circuit, respectively. In C it will be noticed that the molecules nearest K are more darkly shaded. This represents a greater density of the negative electrons at that point. The same will be noticed in A, only that the shading is reversed, the white molecules denoting where the positive particles are dense. This massing of the positive and negative charges at K is practically true. It is similar to the massing of the "lines of force" at the poles of a magnet. The reader understands that the above movement of the charges is not current flow. But in case of A, Fig. 1, it is simply the positive forces lining up ready to rush into the negative neighborhood just across the key points. The same holds true for the negative side C.

Therefore in answer to question 1 we can say that the portions of the open circuit A B K and K C are seats of potential energy, each having, respectively, their positive and negative forces massed together, but held in check ready to launch themselves into each other at the touch of the key. It is understood that if the voltage was sufficiently high the key points would be bridged and the conditions of the circuit would be the same as if the key had been depressed.

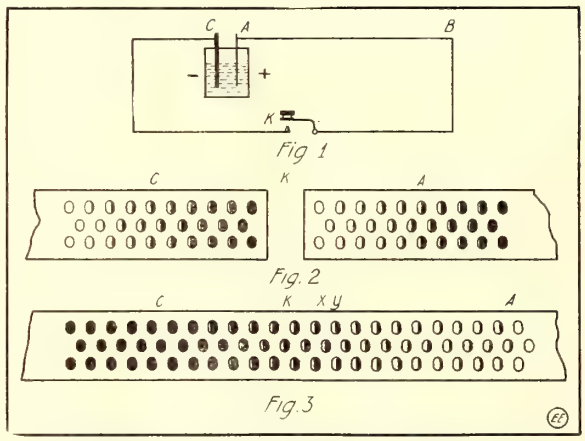


Diagram Indicating How Electrons in a Conductor Communicate a Charge from One Molecule to the Next at the Marvelous Velocity of 186,000 Miles Per Second.

In case of question 2, the moment that contact is made the positive and negative forces that are waiting in the form of potential energy change places; the velocity of the flying forces is truly enormous. Fig. 3 shows K closed. At this instant the opposite forces that are nearest K intermingle, as is shown in the figure directly below K. In this section of the wire it will be seen that the molecules contain equal plus and minus charges. The negative half of the molecules charge is traveling in full force toward A, while the positive half is likewise traveling toward C. It is understood that the molecules are not moving, but the electrons in them. The latter use the molecules for stepping stones, jumping from one to the other in their mad rush back to their home battery plates.

Take for an example the molecules x y, Fig. 3. The negative charge in Y was formerly in X, as also the positive charge in X was formerly in Y. This is how the forces travel through the wire, each force borrowing from the molecule ahead of it an equal quantity of the force of the unlike sign and replacing it with itself. Thus it keeps on this free exchange until it reaches the battery plate, where it is acted upon by the chemical solution. Or in the case of a dynamo being the source of energy it finds its way back to the original armature coil from which it started.

In the above movement of tiny electron the combined movement, which we call an electric current, the molecules of the medium through which they pass, whether it be metal, earth or water, are not practically displaced, but it is their atomic structure that is in turmoil, and as the amperage increases the greater the decomposition of the atoms will be. Also the more molecules are set into vibration.

Therefore in answer to question 2 we can say that after the key is depressed the structure of the wire experiences a molecular upheaval, as the tiny electrons or forces surge through its atomic structure decomposing them and giving to the wire, shall we call it, frictional heat.

* * * * * * *

It has taken years of experimenting to bring the live wire up to its present perfection. The great achievement of transcontinental talk over a telephone wire has been perfected. But taking it altogether the wire is nearing the end of its victorious life.

It has climbed, rung by rung, up the ladder of invention and fame and deserves a good share of the glory in the electrical field. For without it all the great electrical inventions would have been impossible. For example, without the electro-magnet there would never have been any dynamos, telephones or telegraphs. No, not even our wireless telegraph and telephones. These two latter inventions, which the wire has helped to bring about, have paradoxically dealt it the most telling death blow.

Since the trans-Atlantic radio telegraph and telephone are a fact, it no longer requires the "cables" that are lying on the ocean bed to spell out the message in Morse code. It is this new thing that man has invented, the "electro-static wave," that can cause the message to be transmitted across the water with the speed of light (186,000 miles per second).

It is this ethereal agent that is the wire's most deadly opponent. The "cable" is no longer required; it extent is reduced to the length of the wires in the "aerials" on either side of the ocean. This is the wire's one great defeat and others are soon to follow.

The wire must give place to the ether wave. The victory gained by the latter will be slow, but nevertheless will be complete in the end, as Nikola Tesla claims.

What wire used then on apparatus, if any, will be of such a small amount that it will become nearly, if not wholly, obsolete.

BRAZILIAN RADIO ACTIVITIES.

The Brazilian Government has decided to erect wireless telegraph stations in the Rio Grande do Sul Santa Catharina, Sao Thome, Cruziero do Sul, Senna Madureira, Rio Branco, Sao Luiz de Caceres and Porto Murtinho. Steps are being taken to organize a general scheme of radio telegraphy, both on the coast and in the interior.

Making Things

By Thomas Reed

DID your father ever tell you it "Doesn't pay to make anything yourself?" Mine used to. After watching me working like an ant to make a little whirly thing I could have bought for a dollar he casually figured up how much more quickly I could have earned that dollar by sawing wood, and bought the whirly thing. Did Rockefeller drill his own oil wells? No. He hired other people to do it. That's the way he got rich. But this tinkering idea of mine had no standing at all. Life was too short.

There was a little finesse in father's suggestion about the wood-sawing, because he wanted me to contract the wood-sawing habit; but apart from that his attitude was due to his being sore over a certain occasion when he took a hundred dollars out of himself trying to save five dollars. Rockefeller at that time was supposed to have made his fortune by not spending anything. Rockefeller theories keep changing, you know, just like atomic theories.

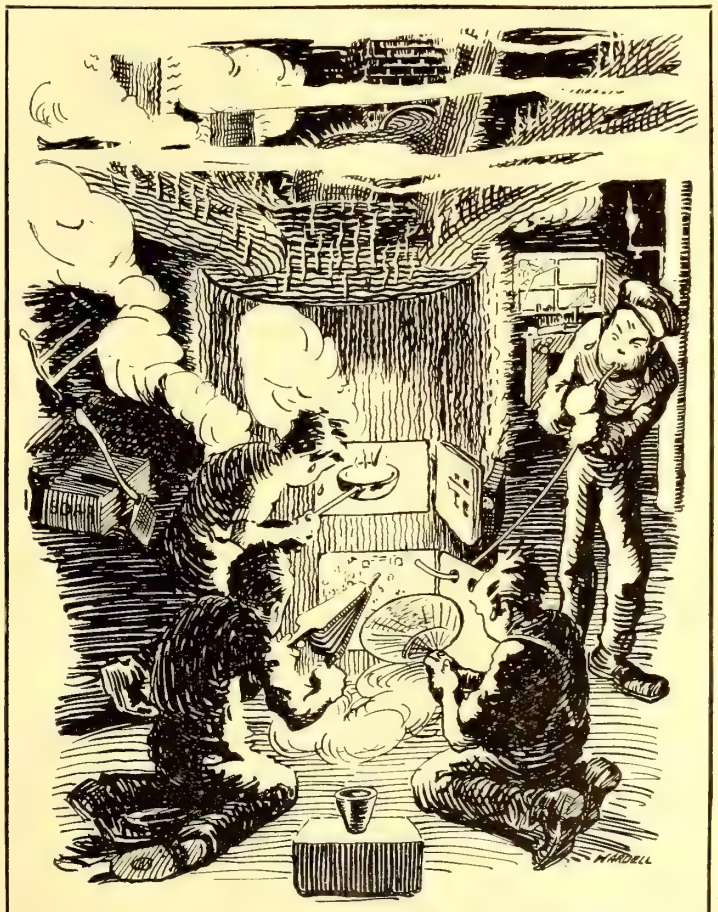
My father, good old man, never tried to make anything, or if he did nobody recognized it as such; but sometimes when he felt strong and had mused on Rockefeller, he would do a little repair-work around the house. I remember when he achieved his masterpiece in this line by mending a broken leg (on a chair, you know—he never dabbled in surgery).

Father had a very complete kit of tools, consisting of a hammer, a gimlet, a plane that got plugged up, and a baking powder can full of rusty screws; and there was a screwdriver in the sewing machine drawer, but that wasn't his, you bet it wasn't!

He retired to the cellar with the so-called tools, together with the chair, and we children kept out of the cellar because—well something in his manner told us he preferred it that way.

After a couple of evenings' hard labor he came up with the chair, and sure enough the leg was cleated on so it looked all right—though he said he guessed we had better not sit on it just yet. Evidently it was convalescing. He had broken his glasses, and his mind had got deeply peeved like a baby after a hard day at the beach. Mother had something she wanted to say to him when the children wa'nt round, about an expression that had escaped him inadvertently; and it did look from certain angles as though it would have been cheaper for father to buy a new chair, or go without and stand up.

But shucks, father, there is a joy in the sense of mastery when you accomplish a thing yourself which far out-weighs the paltry coin saved! (You understand I didn't really hand any such good counsel to father, I only thought it. The current of counsel in our family ran distinctly the other way. There was never any backwash to speak of.)



But whenever I got a good laugh (in my sleeve) on father he was sure to get it back on me before long. For sometimes in my early experiments the saving of my scanty hoard involved such a prodigious expenditure of energy that even to me the result seemed out of proportion—rather a small hang-out, as the fellow says, for so large a wash.

Long ago, when telegraph instruments were the correct thing in amateur circles, the Band of Young Edisons to which I belonged decided to put one over the neighboring bands by making up a real cast-brass set. We hung around the brass foundry and watched operations until we understood what we had to do, and then fell to with great secrecy, as this thing was to be sprung as a crushing surprise. We drew our designs from the pictures in the catalogs and sawed out the patterns with the jig-saw, giving them the slight taper necessary for drawing from the mould, and sandpapering and shellacking them smoothly. So far all was easy, and even the "flask" for holding the sand presented no difficulties. The fine moulding-sand we begged from the foundry-men, who by that time were glad to get rid of us at any price; and after a few trials we were able to draw the patterns and form the sprues.

Then loomed up the melting of the metal; and the enterprise reached that always ticklish stage when some of the settled habits of the family must for the moment give way to the requirements of science. We collected all the old brass and copper on the premises (including one kettle that was missed and formed the subject of an investigation later). This metal in a black-lead crucible was placed in the family furnace, tenderly covered with a fat live coal, and with a forced draft, produced by bellows, fans, and lungs, we gradually forced the heat to the melting-point. The melting-point of the brass I mean; our own was passed far back along the road.

It was in the middle of winter; but before the pouring took place every window in the house was open and the heavy underwear of the family upstairs was scratching just as it does in spring. At one stage somebody started for the fire-alarm box, but was headed off just in time. The output, on a general cooling (of metal, house and anxiety) were a dozen small castings plentifully sprinkled with case-hardened iron particles which defied the file. The costs, as computed that evening by father, who was good at figures, totalled something like $15. (Including coal and repairs to the furnace, but excluding the kettle, which had not at the moment been audited.)

But shucks! Hadn't we *made* the set? The satisfaction of making it was certainly worth more than a paltry $15. If you have the "how-to-make-it" bug, you'll readily appreciate this.

". . . and with a forced draft produced by bellows, fans and lungs, we gradually forced the heat to the melting point."

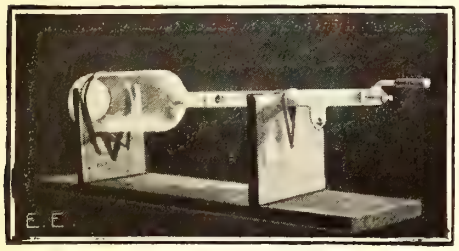
U. S. WIRELESS TO CIRCLE WORLD.

A final step toward linking the United States with its foreign possessions through a great chain of wireless stations was taken recently, when Secretary Daniels, of the navy, approved a contract with the Federal Telegraph Co., of San Francisco, for the equipment of the big radio stations now under construction at San Diego, Cal., Cavite, P. I., and Pearl Harbor, Hawaii.

Completion of these stations within the next year will pave the way for radio communication from Washington not only to the insular possessions, but to almost any point in the world where there may be a receiving plant.

Plans are now being prepared by the Navy Department to increase the power of the existing equipment at Tutuila and Guam, so as to make them a part of this world wireless chain. The intermediate stations at Boston, New Orleans, Point Loma, Chicago and Guantanamo already have been strengthened and are able to relay messages from ships at sea to Washington via the Arlington, Va., towers.

Further advancement in radio development will be made this year at Charleston, S. C., San Juan, Key West, Puget Sound, Cordova and Mare Island.



The new stations at Pearl Harbor and Cavite will be the most powerful in the world. They will be equipped with apparatus for exchanging messages over an area of approximately 4,700 miles, the greatest distance ever attained by radio plants in daily use. Each will maintain direct communication with San Diego, the Canal Zone and the Arlington stations, and will be able to sweep the Pacific Ocean from the Philippine Islands and to Alaska and the Canal Zone.

Use of the Braun-Tube for Research Work on Electric Oscillating Currents

By Prof. Dr. Ferdinand Braun, University of Strassburg i/Els.

*[By invitation of the editor of The Electrical Experimenter, I am pleased to give a short essay on the above mentioned subject.—Author.]**

I WILL begin with a few words on the *Cathodic Rays*. Suppose you have a glass tube in which the air is rarefied to the extent of that existent in the so-

Typical Form of Braun-Tube.

called Geissler tubes. An electric current passing through this tube will follow a path from the anode to the cathode, showing the well-known luminous effect. But if the gas is more and more rarefied this usual light effect disappears and the cathodic rays begin to develop themselves. They do not follow the path (if we may so term it) of the current, but are emitted from the cathode normally to its surface straight into the gas. The anode may be placed anywhere in the tube, one method being shown in Fig. 1. These rays impinge on the glass wall and produce an intense fluorescent light, which is usually green in color.

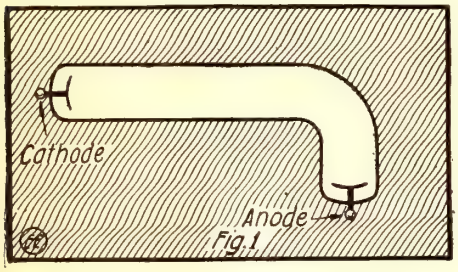


Fig. 1. Simple Cathode Ray Tube.

The cathode rays are streams of negatively charged particles (the electrons) flying through the vacuum with terrific velocity, this being between one-tenth to one-half and more of the velocity of the light (186,000 miles per second). These rays are practically without any inertia and represent electric currents in conductors; they are "flexible" in every direction. If you pass a cathodic ray between two metal plates (Fig. 2), one of which may be charged positively and the other negatively, the path of the cathode ray is changed in the electric field of the small condenser

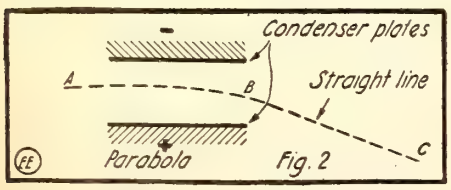

Fig. 2 Showing Deflection of Cathode Ray.

into the form of a parabola AB. After leaving this field it continues its way as a straight line BC. If the charge of the condenser varies periodically, the point C will oscillate in syntony with the time period of the charges. It produces in this manner an oscillating light point on the wall. This will be green and relatively weak on glass; blue and very much brighter on sulphide of calcium, and a very bright green on sulphide of zinc.

If the frequency of the charges varies at the rate of, say 100, the oscillations of the light point on a phosphorescent screen will also be 100; and if the frequency goes up to a thousand or a *hundred thousand,* the cathodic ray will *always follow and never lag.*

The effect of magnetic forces on this ray is the same as that on a current; the ray follows the magnetic force and is deflected in a direction perpendicular to such a force. Suppose you have a magnet coil, as Fig. 3, and pass an alternating current through it. If a cathodic ray lies in the field of the magnet it will be set in oscillation, according to the time period of the current.

The Braun-tube (Fig. 4) depends upon these properties, and can now be explained

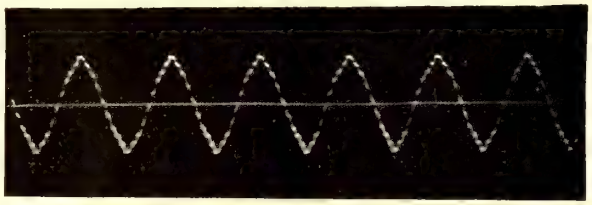

Fig. 6. Braun-Tube Oscillogram of 50 Cycle A. C. With Higher Harmonics.

in a few words. It should be called a cathodic ray tube, which is the term by which I introduced it into the scientific world, but as it was later called the Braun-tube I shall use this name for the sake of brevity.

Referring to Fig. 4, C is the cathode electrode, A is the anode and B is a small aperture made in a glass or metal diaphragm. As these materials do not allow cathodic rays to pass through, only a small stream of them pass through the opening, thus to create a "light image" on the fluorescent screen D. The tube is

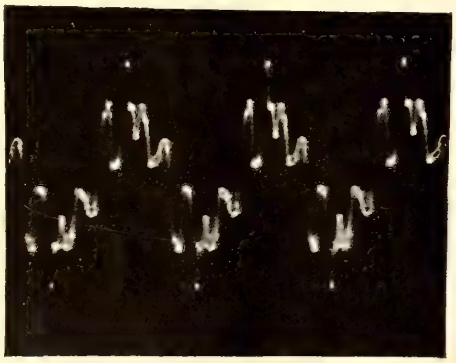

Fig. 7. Higher Harmonics of Fig. 6, Enlarged. N = 1,500.

evacuated to a high degree, and only by experiment can it be ascertained what the best degree of evacuation is. It can be estimated, however, by employing a spark gap placed parallel to the electrodes of the tube; a 2, 4 or 8 mm. spark length will be found the best as a rule. The brightness of the fluorescent spot depends upon the degree of the evacuation, as the higher this is the brighter will be the light, but the less will be the sensitiveness of the deflection when excited by a given electric or magnetic field.

The diameter of the light spot can be diminished by magnetic coils surrounding the tube, through which an electric current flows. The intensity of the current (am-

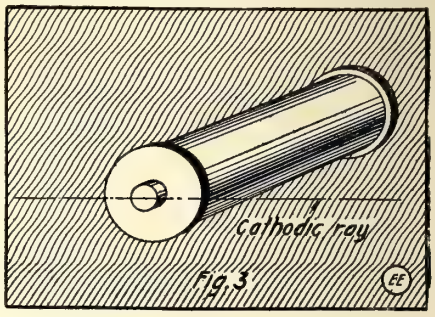

Fig. 3. Cathodic Rays Are Acted Upon by Magnets.

pere-turns) and the best situation of the coil is to be found out only by experiment. The smaller the spot is the brighter it becomes. While the sensitiveness is diminished by this operation, it is not to any disturbing degree.

A static machine of 20 or more discs may be used as a source of high-tension electric current for operating the Braun tube. Smaller machines, of course, can be used, but the intensity of the spot will not be so great. The best source of current would be a battery of some thousand accumulators, which may be of small size. L. Chaffee used the large battery of Professor Trowbridge, which developed in

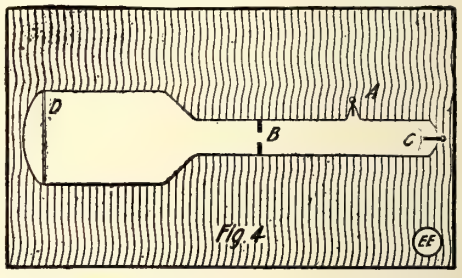

Fig. 4. Section of Braun-Tube.

most cases 20,000 volts. Induction coils should not be used, as the deflection depends upon the voltage of the current.

By using a Wehnelt cathode (i. e., an electrode covered with a spot of calcium oxide and heated by an electric current) a voltage of 1,600, 1,000 and even 600 volts is

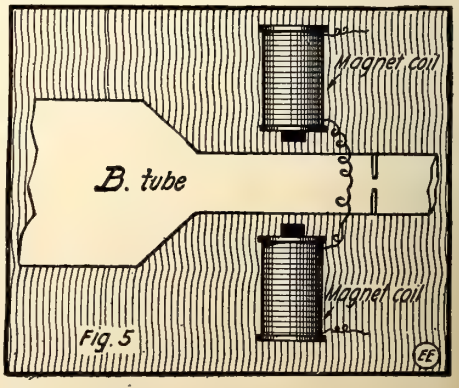

Fig. 5. Magnetic Control for Braun-Tube Ray.

sufficient for producing cathodic rays, although they are not very sensitive.

*This article was prepared exclusively for The Electrical Experimenter.

The great advantage of the Braun tube is that it will record a pulsating electric

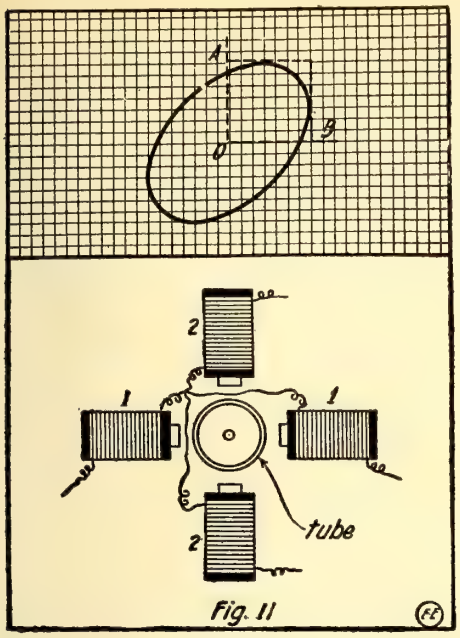

Fig. 11. Magnets Placed About Tube and Connected to Give a Phase Difference. The Curve Resultant is Seen Above.

current of frequencies which are impossible of registration in any other way. The difference between a galvanometer and a Braun tube may be explained by an illustration. It is a well-known law that the electro-motive force induced in a conductor which is moved in a magnetic field is proportional to the velocity. This cannot be demonstrated by a galvanometer, the deflection of which does not depend upon the instantaneous value of the current, but on the movement of a swinging element of definite inertia. The deflection of the cathodic ray depends only on the instantaneous value of the current or voltage. Consider a coil A connected with the indicator coil of the tube acting upon the rays. Give the coil A a small movement in a magnetic field. If the speed is slow the deflection will be small; as the speed is increased the deflection will be increased. *The absence of inertia* of the cathode ray enables one to gauge the static field by this tube then. This is extremely difficult to do with any other apparatus which we have at present.

I shall give several examples for the use of the Braun-tube:

1. *The Form of Vibration.*—There may be one, but better two "indicator coils;" one on the left, the other on the right side of the tube, as shown in Fig. 5. Let us suppose for the sake of simplicity that an alternating current is passed through the

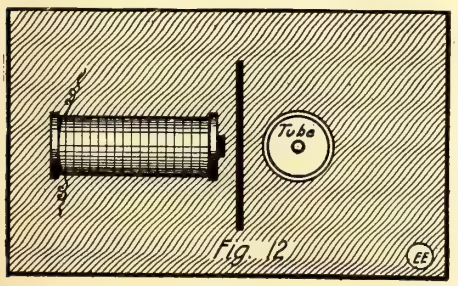

Fig. 12. Experiment to Demonstrate Screening Effect of Iron Plate Before Magnet.

coils. The light spot assumes the form of a straight line, the length of which measures the *double amplitude* of the current. If a revolving mirror is placed in such a manner as to catch the phosphorescent spot on the screen we can "see" the vibrations, literally speaking. If a moving film is passed near the mirror it will photograph the curve. The light of the spot in good tubes is strong enough to permit of taking photographs of it up to frequencies of about 1,200 *per second.*

Professor Zenneck has used the tube in many of his researches, and I herewith give several illustration of his work.**

Fig. 6 represents the vibration form from the current of a machine connected in a circuit with ohmic resistance only; the frequency (N) is 50. The fine points demonstrate higher harmonics (N being about 1,500). These latter are clearer in Fig. 7. There is a condenser of 10 Microfarads in this circuit.

Fig. 8 is taken with a current N = 1,080.

Figs. 9 and 10 are images of damped, coupled circuits (N = 250); Fig. 9 for loose coupling; Fig. 10 for close coupling.

The greater the frequency the greater the difficulty encountered in taking a momentary or instantaneous photograph. But if we can devise an arrangement which will cause the "light spot" to pursue exactly the same closed curve on the screen; for instance 100,000 times or more, we shall then be able to take a photograph of this standing figure. In this manner, the details of

Fig. 9. Loose-coupled, Damped Discharge.

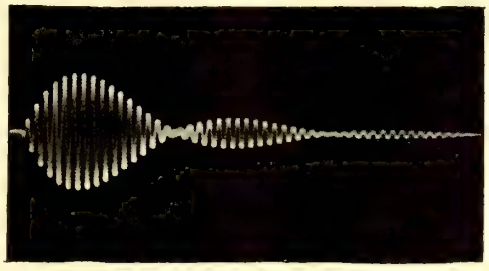

Fig. 10. Close-Coupled, Damped Discharge.

Fig. 8. Oscillogram of 1,000 Cycle Damped Current.

which cannot be explained here, as it will require too much space, photographs have been taken of oscillating currents at frequencies up to 1,000,000 or 1,500,000 cycles per second.

Let us suppose we have two sets of coils, 1, 1 and 2, 2 (Fig. 11), of which the axes are crossed at right angles. An alternating current of the same time period is sent through each pair of coils, but the current in the pair 1, 1 may have another phase than that in the second pair 2, 2. The "light spot" now describes an ellipse (the so-called Lissajou's "curve") on the screen. OA measures in a relative way the field resulting from the coil pair 1, 1, and OB that of the coils 2, 2. The phase difference is expressed by the situation of the axis of the ellipse. For the phase difference of 0°

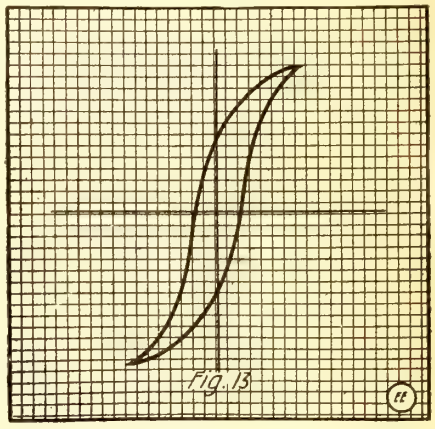

Fig. 13. Hysteresis Curve Obtained by Placing Iron in Coil.

and 180°, you observe a straight line; for 90° difference, an ellipse with axes vertical and horizontal. In any other case the ellipse would be in a different situation.

If the time period of the two interfering currents is not the same, but in the ratio 1 : 2, 2 : 3, etc., you observe other well-known curves.

We may now consider some lecture experiments. For simplicity we take only one coil (Fig. 12). We place a number of fine iron or nickel wires in the coil and the deflection of the spot increases. We bring a thin plate of the same materials in front of the coil and the deflection decreases; we now have a screening effect.

We next use crossed coils (Fig. 11). All the coils may be connected in series, but the two coils 1, 1 are connected in this manner so that their magnetic fields at their meeting place in the cathodic rays are opposed to each other. So we see on the screen a horizontal line measuring the (double) amplitude of the alternating magnetic field of the coils 2, 2. If we introduce into one or two of the coils a quantity of fine iron wire, then we observe a curve like that at Fig. 13. It is the hysteresis curve of the material; of course, not the true form of it, as the iron core is not a closed one and thus the curve is disturbed by the reaction of the free poles. However, it is clearly demonstrated by the curve that the magnetization of the iron, nickel, etc., depends upon the earlier magnetic states (the magnetic history of the piece).

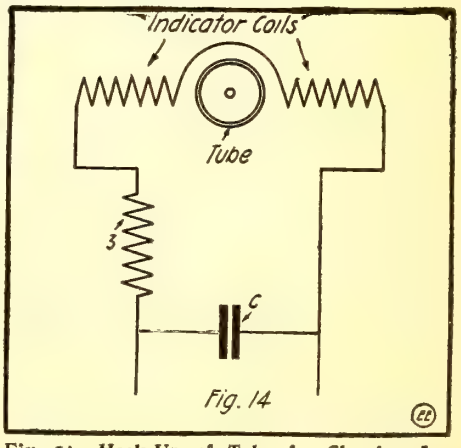

Fig. 14. Hook-Up of Tube for Showing Impedance Effect.

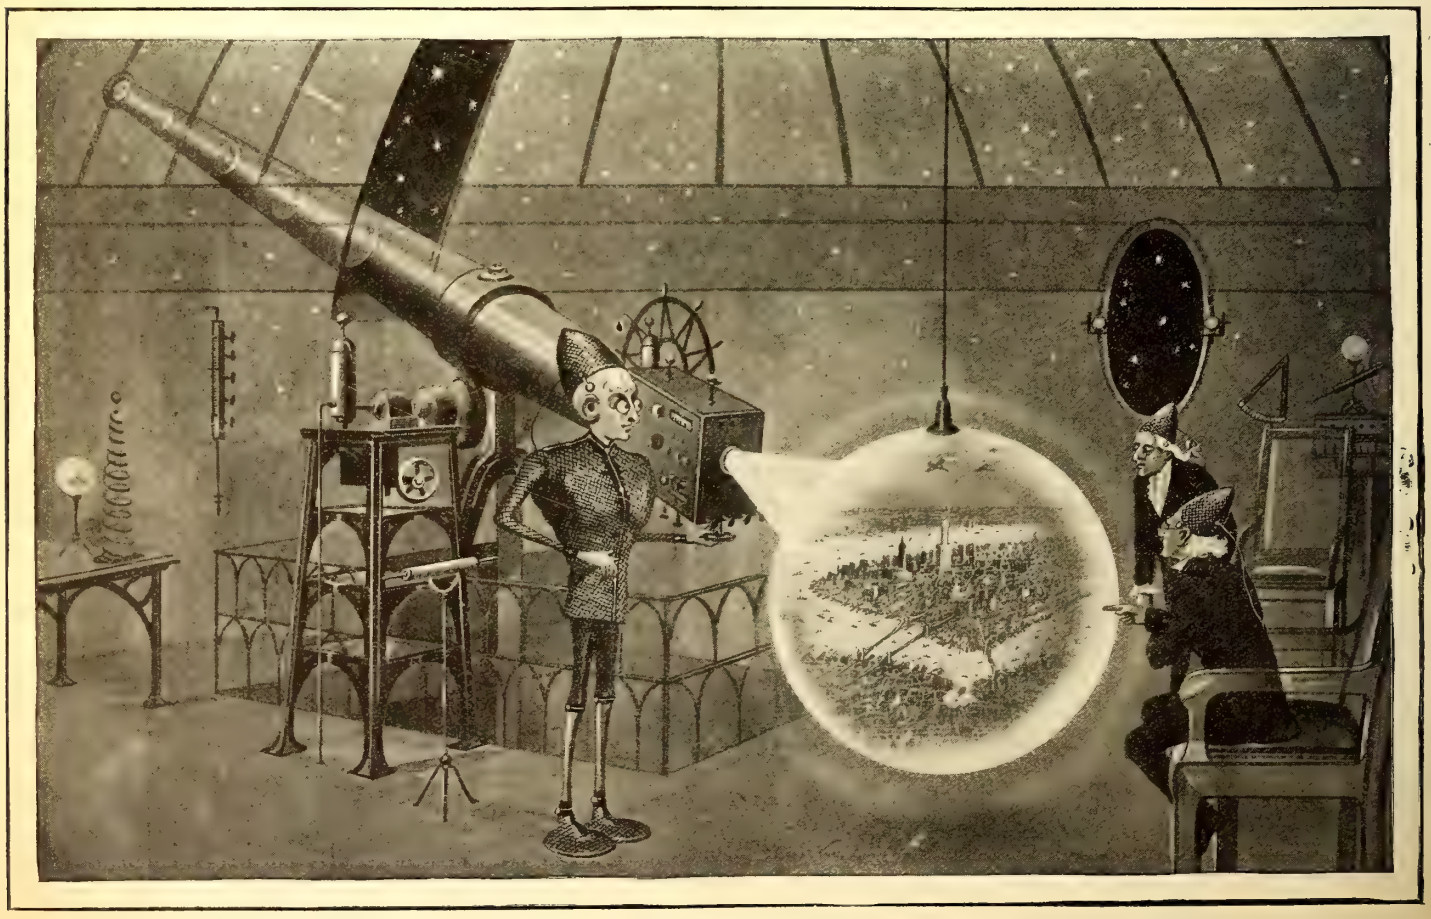
Baron Münchhausen's New Scientific Adventures

By Hugo Gernsback

The Planets at Close Range

WHAT is modesty? From childhood up I have been taught that this quality was more or less of a virtue, but developments of late cause me to believe that it is hypocrisy, plain and simple. I have found since, that modesty is something in us which we wish to make other people believe and which they realize perfectly is not so, or perhaps trying to make the other fellow believe something that you know isn't so. All of which might have a passing interest for you and then again it might not; probably the latter is quite true. Perhaps the above may have a certain bearing on this story and on the other hand it might not; probably that is quite true also.



I have no fault to find with the Martians, and I believe implicitly what Münchhausen has been telling us about the utter frankness of the Martians and their habits. Only it doesn't work on earth, or at least it doesn't work in Yanktown. As will be remembered, Münchhausen told us a little while ago that the Martians live in transparent houses, for reasons best known to themselves. As will also be remembered, he told us that anything that is worth doing —on Mars—is worth doing with everyone looking on. He told us that non-transparent rooms make for nothing but laziness and vice; also that when your actions are open to the entire world you are more apt to lead an upright life than otherwise. We were told that for that reason no false make-believe life was lived on Mars as is the case on earth.

I tried the Martian recipe the other day, and I must confess here that it was a dismal failure. Now everyone knows, of course, that everyone else is apt to take a bath once in a while for strictly personal reasons, the only difference being that the frequency varies with some individuals according to taste and according to the available water as well as soap supply. I know that *you* take a bath and you know that *I* take a bath; certainly there is no secret about that. Nobody should find fault with such universal custom. But when I tried it the other day, leaving my bathroom window wide open, it somehow didn't work out according to the Martian recipe, at least Officer Mulligan, on the beat, who I believe had not read about the Martians' habits, didn't approve of my custom and very promptly arrested me when a big crowd collected in front of my bathroom, which happens to be on the ground floor. I have since given up trying to convert antiquated humans living on an uncivilized globe, to Martian standards of civilization. Perhaps in a hundred thousand years from now humanity will not feel so peevish about it, but until that date I shall believe in the proverb, "When in Rome bathe as the Romans bathe."

* * *

Promptly, as usual, that evening Münchhausen "called." On the minute at 11 p.m. the familiar whining, screeching sound reverberated in my 'phones, and immediately following the Baron's sepulchral rasping voice was heard once more.

"Good evening, my dear boy; mighty sorry I had to cut myself so short last night but, at that, I believe that the telegraphone wire on my radiotomatic was full to capacity before I stopped speaking. If my memory serves me right, I believe I had been telling you about the Martian elevated cities—and how the Martians do away with their choking dust filling up the atmosphere near the ground. I told you how the elevated Martian cities had perforated, metallic streets so that the fine dust would filter through the perforations thence to fall down to the ground. Possibly it occurred to you that in a few hundred years this dust settling on the ground below would rise high enough to fill up the 500 feet of intervening space between the ground and the elevated streets. If no means were taken to do away with such accumulating dust and sand this, of course, would be the result, but nothing of the sort happens, for Martian ingenuity naturally precludes any such occurrence. But how is the sand and dust done away with? It is a very simple mater indeed. Mars, as we know, is a very ancient world, which has cooled for centuries back. There are no more live volcanoes on Mars, for the very simple reason that the inside of the planet has cooled long ago, the same as is the case on your Moon to-day. Take the earth, which is a much younger heavenly body than Mars. On earth, as yet, the interior is in a molten state, proven by the fact that volcanoes still exist, as well as hot springs. Hot gases must naturally abound for if this were not the case there would be no pressure to force the molten lava through the craters of the terrestrial volcanoes. But a molten mass as well as hot gases take up room. Suppose the interior of the world

. . . Again the knobs were manipulated, and we now saw a most marvelous view of the City of New York, as if viewed by an aviator a few thousand feet above the earth. . . .

WHEN the famous Italian astronomer Schiaparelli in 1877 first glimpsed the Martian "canals" through his modest telescope, the world at large believed his observations to be a mere optical illusion. Time and progress, however, have so improved our telescopes, such as, for instance, the one at the Flagstaff Observatory, that on account of the immense magnifying power, the "canals" stand forth sharp and unmistakable. How far can science go in increasing telescopic magnification? Will we ever see the Martians themselves through the telescope? Read this instalment and see.

would cool to-day; immense hollows or voids would naturally be created inside of the earth. This is precisely the case of Mars, which has now immense hollows and voids, and these are used for many different purposes by the Martians in their conquest of their dying world, as I shall show later.

"For one thing, every few miles beneath all Martian cities immense funnel-shaped holes are drilled till one of the voids is reached. The openings of these holes are constantly kept clear by the Martian engineers. How simple, then, is the thought of pushing the surplus desert dust and sand into these holes to do away with the sand nuisance. Very ingenious means are used in thus getting rid of the dust, and after every sandstorm, which are more or less frequent, the surplus sand and dust rolling on from the open deserts is forced into these openings as fast as it develops. Of course, it is impossible to thus get rid of all of the sand, but it helps in a certain degree to make life bearable on the planet.

"You will remember in my report of last night that on that evening Flitternix and I were on the Planet Ruler's mansion on top of the building looking down on the vast Martian capital that lay below us. We were watching in amazement the gravitationless fliers, which are used by the Martians almost exclusively for their transportation. I have told you previously that these fliers are flat, pancake-like, metallic bodies with three masts spaced equally distant from the center. We saw thousands of these gliding noiselessly through the thin Martian air, their intense yellow propelling light shafts plying all over the sky and over the ground. It is indeed an inspiring sight to see thousands of these flyers in the air all the time, and the spectacle becomes even more amazing when night comes. The yellow emanation rays are highly luminous, and for that reason no other searchlight is required. As long as I have been on Mars I have never witnessed a collision, although these astonishing vehicles fly so close to each other that one sometimes thinks they must collide. Each Martian building on one of its sides has a metallic landing platform extending at right angles from the building. There the fliers land to deposit passengers or freight.

"We were watching this amazing spectacle; it was in the early evening and the sun had just set. Being accustomed to twilight we naturally thought it would stay light for some time to come, but we were surprised that no sooner had the sun disappeared behind the western horizon than the landscape became pitch black. I was about to comment upon this unusual phenomenon when Flitternix forestalled my questions, launching into his usual astronomical reflections.

"'My dear Baron,' said he, 'no doubt you have been surprised that there is no twilight on Mars, but the reason, of course, is very simple. The earth to which you are accustomed has a very dense atmosphere. After the sun has sunk below the horizon its rays still strike the atmosphere above you, although you cannot see the sun itself. Naturally, it does not become dark immediately for the reason that the light is diffused in the air above you up to about 30 miles above the surface of the earth. In other words, the sun on earth acts exactly like a searchlight which is hidden from your sight while its light shaft plies above your head. You can see the light perfectly over head, and the sun's rays act in a similar manner on earth.

"'On Mars, however, the atmosphere is very thin and only reaches a comparatively few miles above the surface of the planet. Therefore but little light is diffused in an attenuated atmosphere, as is well known to you, and for this reason no twilight can exist on Mars; this you have just witnessed. As previously experienced during our stay on the moon, where there is no air of any consequence, everything must be dead black or white, there cannot be any grays in the transition from light to dark. On Mars, of course, such extremes do not exist for the reason that there is still some atmosphere to diffuse the light.'

"While Flitternix was still talking we saw the marvelous sight of the city below us being illuminated at the precise moment when the sun had sunk out of sight.

"Nearly every structure and building on Mars is of the same height. On top of their cone-shaped roofs several immense, transparent spheres are spaced 20 to 25 feet apart. These balls are usually arranged in a circle or in an equilateral triangle. No sooner has it become dark on Mars than these transparent balls emit a dazzling rose-white light. This light does not emanate from these globes in form of a shaft, as we are accustomed to from searchlight illumination. Quite the contrary; the light spreads out in all directions for a distance of over 500 feet. The strange fact is that the light is as strong at this distance as it is in the immediate vicinity of the spheres. As a matter of fact, it is strongest about 25 feet from the balls themselves. Inasmuch as every building and every elevated structure gives forth this spreading light every object within 500 feet of the light balls is illuminated almost as strongly as in daytime with the sun shining. This creates the curious result that when walking in a Martian street at nighttime daylight is simulated in a perfect manner and it is hard to realize that it is not, indeed, sunlight that is pouring down upon you. Not only do these transparent light balls give out light rays, but the rays also emanate heat prodigiously. This is quite necessary. I have spoken before of the fact that the Martian atmosphere is very thin and attenuated. Naturally such a thin blanket of air cannot retain the solar heat during the night, and for that reason the nights on Mars are extremely cold. This is true of the temperate as well as of the other zones. For this reason the light rays of which I spoke before have been made to radiate heat as well, otherwise it would be too cold to walk on the streets after nightfall. As it is, the temperature is but slightly below that which exists at noon time. It will, of course, be plain to you that as soon as the sun rises in the morning the light balls are switched off, for then there is no further use for them.

"You might think that it would be an enormous undertaking to light and heat vast cities by such artificial means, but the cunning Martian wherever possible lets Nature do all of his hard work. I have already shown to you how the Martians moved the water in their canals and waterways by means of the all-dominant sun, and if our luminary can perform useful work during the daytime why not use it at night? I have mentioned before how the Martians harnessed the sun's energy, storing up enough power to use the surplus after sunset. Thus we find the curious phenomenon on Mars that the intelligent beings inhabiting this planet have harnessed enough energy from the sun during the daytime that when released it furnishes them with light and heat during the night. The sun's energy during the daytime is converted into electricity, as I have already shown, and is then stored for further use. Consequently the night illumination and heat is derived primarily from the sun and costs the Martians nothing. When you consider how crudely you humans use your energy it must dawn upon you that you are still very young children. At that the inhabitants of the earth are doing precisely what the Martians are doing except doing it in a very bad way. You are already deriving 100 per cent. of your light, heat and power from the sun *indirectly*. The coal which you are mining this minute derives its original energy from the sun. Millions of years ago great forests—which were directly a product of the sun—sunk into the earth, thereby carbonizing the wood. This wood you are burning as coal to-day. In other words, you are using sun-power, stored millions of years ago. Even your water-falls from which you derive your power are directly dependent upon the sun. Without the sun to suck up the water from the seas into cloud form, your water-falls would run dry within one week. The Martians, who have long ago exhausted such means of utilizing the sun-power, are now using the sun-power supplied by the sun yesterday. You on earth to-day are using sun-power stored millions of years ago. After your coal supply gives out and after your water supply is not as abundant as it is at present you will revert to exactly the same means as do the Martians on their dying planet to-day.

"After dinner the Planet Ruler took us to a vast circular room high up in the mansion, which we presumed to be his study. The thing that struck us most forcibly at once was an enormous glass-like transparent rod which broke through one of the transparent walls of the room. This rod probably measured two or three feet in diameter, and as far as we could see it it was about 15 feet in length. We afterwards found out that it extended 75 feet beyond the building, pointing toward the sky. The thought immediately forced itself upon us that it was a form of telescope, which indeed it was. It was arranged in telescope fashion and by means of machinery located outside of the room, the far end could be made to point to any object in space. As the mansion of the Planet Ruler revolves around its axis, as I have already mentioned to you previously, the telescope may thus be pointed at

Marvels of Modern Physics

By Rogers D. Rusk

Assistant Instructor in Physics, Ohio Wesleyan University

Invisible Radiations.

IN very recent years many forms of radiation have been discovered which do not affect the eye, and hence are invisible. Already the benefits which have resulted to mankind have been of infinite value, even though this branch of physics is only in the infancy of its development.

Radiations may be roughly divided into

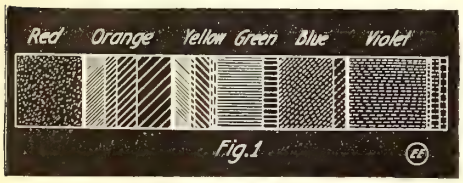

Fig. 1. How the Colors of the Visible Spectrum Range Themselves.

two general classes; (1) those which consist of material particles traveling at high rates of speed, and (2) those which consist, not of material particles but of vibrations in the *ether* similar in nature to ordinary light waves. The first of these classes we will leave until we have considered the various kinds of *ether waves*.

Consider a beam of sunlight passed through a prism. The different lengths of light are spread out in a broad band of colors. The same thing happens when sunlight is reflected and refracted by raindrops, and we see the rainbow. When the light waves strike the prism at an angle they are slowed down in speed and also bent a little from their original path. The violet waves being the shortest, are bent the most; and the red waves, being longest, are bent least of all. The colors now range themselves, as shown in Fig. 1, in the order of their wave lengths.

The perfect blending of the colors thus demonstrates clearly that the waves vary gradually in length, from the longest to the shortest, but it must not be thought that they suddenly cease to exist at the upper edge of the violet or the lower edge of the

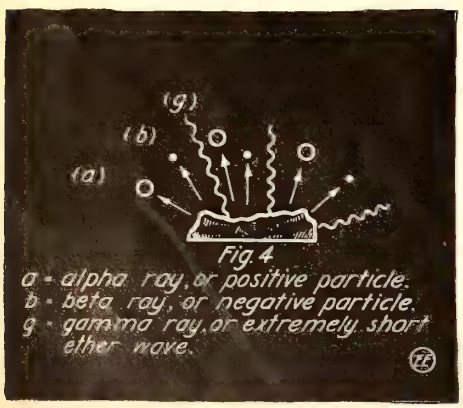

Fig. 4. How Invisible Radiations Occur About Radio-Active Substances, Such as Uranium.

red. It is quite true our powers of visual perception cease very suddenly at those points, but it is easily proved that waves of other lengths exist beyond them. Those of us who are imaginative often wonder what strange colors might be beyond the violet and the red, if only they were visible.

Red light has been measured as having a wave length of 1/37,000 of an inch, and violet a wave length of 1/70,000 of an inch, while the orange, yellow, green and blue are intermediate. As we know that light travels at the velocity of 186,000 miles per second, we can easily calculate the number of vibrations made in a second by each kind of wave. (See Fig. 5.) A single wave, then, travels in a second about 10,000,000,000 inches, and 10,000,000,000 times 37,000 equals 370,000,000,000,000, or a red light wave vibrates approximately 400 million-million times per second. In the case of violet light the vibration rate is about 700 million-million times per second. The wave lengths cited below will give a clearer idea of this factor.

COMPARISON OF WAVE-LENGTHS.

Wave.	Length in cm.
Hertzian wave.*	1,500,000.
Hertzian wave.†	0.5
Heat waves (longest)	0.13
Red light	0.000077
Violet light	0.000036
Ultra violet.‡	0.000010
X-rays	0.00000001
Gamma rays	0.000000001

* Longest yet generated.
† Shortest yet generated.
‡ Shortest in solar spectrum.

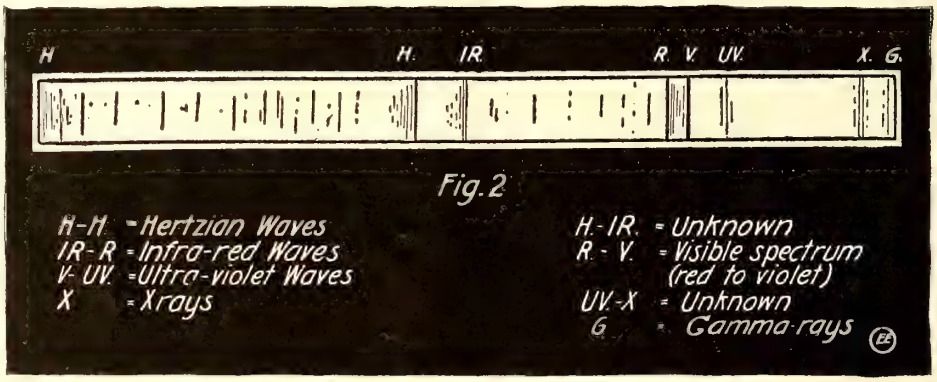

Fig. 2. Extended or Invisible Spectrum Shown Diagrammatically.

The visible spectrum can be divided into three general divisions—the red and orange, or heat portion; the yellow and green, or luminous portion; and the blue and violet, or chemical portion, sometimes called the actinic.

Langley traced the longer rays beyond the visible eye (known as the infra-red) for 10 octaves below the visible spectrum, largely by means of an instrument called the *bolometer*. An octave in light, it may be stated, is similar to an octave in music; that is, it is the interval between two lengths of waves, one of which is twice the other. The visible spectrum, then, is approximately one octave. Langley's bolometer was merely a sensitive Wheatstone bridge with one arm made of blackened platinum. Infra-red rays falling on the blackened arm would be absorbed, and the resulting change of resistance due to a rise in temperature would be apparent from the deflection of the galvanometer. Thus the change in temperature could be measured.

The ultra-violet rays, on account of their chemical or actinic properties, have been easily traced by using the common photographic plate for about two octaves above the violet. Waves shorter than this are absorbed by the air.

It must not be thought that the three classes of waves in the visible spectrum were so named because they possessed one property alone. Any of the waves possesses all three properties to a greater or less degree. The classification only serves to emphasize the more prominent characteristic of each. The close relation of the various waves can be seen by taking a cannon ball and heating it. At first very

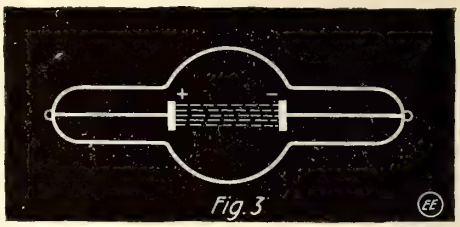

Fig. 3. Simple Tube for Studying Electric Discharges in Vacua.

long waves are given off, and as the iron becomes hotter the waves become shorter. Finally red light is emitted, and then the cannon ball passes through the stages from red to white heat. That heat waves are only long, invisible light waves is readily seen.

The great scientist Hertz, in addition, proved that electric waves produced by the spark discharge of an induction coil are identical in nature with light waves, and are reflected, refracted and polarized according to the same laws as light waves. Hertz in his experiments used waves of eight or nine meters length. Since then, in wireless telegraphy and laboratory research, waves have been produced directly, varying in length from several thousand meters to only few millimeters. The shortest, however, are many times longer than the longest visible wave.

Radio detectors are able to detect these long waves due to their heating and other manifestations.

These relations which we have noted lead us to the thought that a complete or extended spectrum can be diagrammed in the same manner as the visible spectrum, and

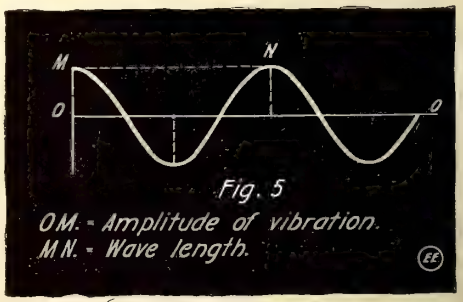

Fig. 5. Components of a Transverse Vibration or Wave.

in Fig. 2 we have the different waves arranged in the order of their length, from those of thousands of feet to those of only a few trillionths of an inch wave length. Such a comparison is valuable. More striking phenomena have been noted in the

The RADIO LEAGUE of AMERICA

HONORARY MEMBERS
CAPT. W.H.G. BULLARD, U.S.N. NIKOLA TESLA.
PROF. REGINALD FESSENDEN. DR. LEE DE FOREST.

Manager, H. Gernsback

How to Organize and Conduct a Radio Club

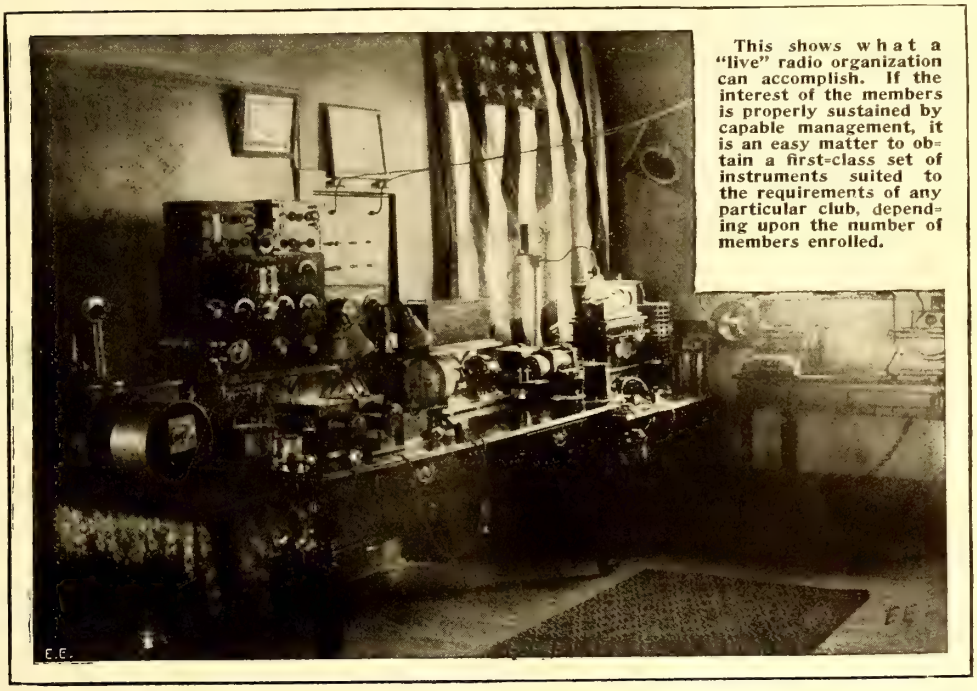
(Concluded)

To Effect an Organization.

CONSIDERING that a regular club is to be organized with fifteen to twenty or more charter members, the following parliamentary rules are useful:

After a call to order has been given for a stated meeting or to effect a certain organization, any person interested, or appointed by common consent, may call the meeting to order and state the reason for the assemblage, asking any of those assembled to nominate a chairman. He puts motions or nominations to vote until the majority agree upon one man who is declared elected, takes the chair and proceeds to conduct an election of secretary and the other necessary officers required for the time being, until a permanent organization can be effected; these officers can be made permanent if the assemblage so agrees. The organization also can be made permanent by a vote. The chairman appoints a committee to draft a constitution, by-laws and rules of order, which should contain at least these articles:

1. The name and object of the society. 2. Qualifications of membership. 3. Officers, how elected (i. e., by oral or written vote) and duties. 4. Meetings of the society. 5. How to amend the constitution. At a second meeting the constitution should be adopted and signed by all who wish to become members; by-laws can be adopted and a committee appointed to nominate permanent officers to be elected at this or a future meeting.



Duties of the Several Officers.

The chairman or president enforces the rules adopted; calls the house to order; announces its business; sustains order; explains and decides questions of order, with the provision of reversal being given the house; appoints all committees not otherwise provided for; recognizes speakers; sumbits motions; puts to vote all questions regularly moved; announces results; signs official documents. He is given precedence in speaking on questions of order and decides tie votes.

The vice-president acts for the president in his absence. In his absence the secretary acts.

The secretary records the proceedings of the organization; writes all letters; calls the roll for absentees or votes; reads minutes of previous meeting; reads all papers and documents to the organization; keeps committees informed of their work; signs all records and is responsible for all papers belonging to the organization. The secretary can act in the absence of both president and vice-president to appoint a temporary chairman.

The corresponding secretary has charge of all correspondence received or sent out by the organization.

This shows what a "live" radio organization can accomplish. If the interest of the members is properly sustained by capable management, it is an easy matter to obtain a first-class set of instruments suited to the requirements of any particular club, depending upon the number of members enrolled.

Extraordinarily fine and complete wireless station owned by the Colorado Wireless Association, of Denver, Colo. Workshop and club room (here shown) obtained through courtesy of local Y. M. C. A. Transmitting equipment includes two 1-Kw. rotary quenched spark sets giving a night sending range of 1,000 miles (maximum 1,500 miles). Receiving apparatus incorporates ultra-audion and two-step amplifiers with tuning inductances for waves up to 20,000 meters. They hear practically everything in the ether between Germany and Honolulu, Alaska and Panama. The station's call is K I X (limited commercial government license). Secretary's address, Lawrence P. Hough, 1060 Josephine St., Denver, Colo.

The treasurer handles all moneys of the organization, receiving and disbursing as ordered by vote, and accounts for it to the society.

Length of Time Which Office is Held.

Officers should be elected to serve for six months, or at the longest for one year.

Membership.

Membership implies that a person has been regularly received according to the rules of the organization and has duly signed the constitution. A member must obtain the consent of the chairman before he can address the house; must speak only on the subject in hand, unless otherwise permitted; must give due respect to fellow members in his speech and promptly yield to the chairman's call to order. A majority of members constitutes a quorum, unless otherwise designated by the constitution.

Motions.

A motion can be made by any member who properly obtains the audience of the house, but after a motion has been seconded it cannot be recalled except by the permission of the house. No motion can be made while a member is speaking nor while another motion is before the house. Motions must be written if so desired by any member or vote of the house.

General Order of Motions.

1. To appoint a time for adjournment, B. 2. To adjourn for unlimited recess, A E F. 3. Orders of the day, A E H N. 4. To lay upon the table, A E G. 5. Call for the previous question, A E M. 6. To postpone action to a fixed time, C. 7. To refer to committee, D. 8. To amend or to reconsider, I K. 9. To suppress or postpone indefinitely, D E.

Rules Governing Motions.

A. Not debatable. B. Not debatable while another question is before the house. C. Limited debate allowable on propriety of postponement. D. Concerns the main question. E. Only amendment permitted is a motion to adjourn. F. Cannot be reconsidered. G. If voted for affirmatively, cannot be reconsidered. H. In order even when another has the floor. I. Precedes all except adjournment, but cannot be put by any person voting with the minority. K. A motion to amend an amendment cannot be sustained. L. The chair is sustained when an appeal to the house results in a tie. M. Requires a two-thirds vote, unless special ruling is made. N. No second required.

A Question.

A question should be put first on the affirmative side, and then on the negative. If any doubt arises as to results, a division of the house may be had. A question can be lost in a tie unless the chairman casts the deciding vote affirmatively. After a question has been put, it is not debatable until after the affirmative is put, when anyone, not having spoken before, may speak before the negative is put. Several questions in one may be divided and taken separately. No one can vote on a question af-

RADIO DEPARTMENT

Radio Range and Direction Now Found by Instruments

INESTIMABLE in value has been the boon conferred upon man by the invention and development of wireless telegraphy, but its full value has never yet been attained, because of serious defects.

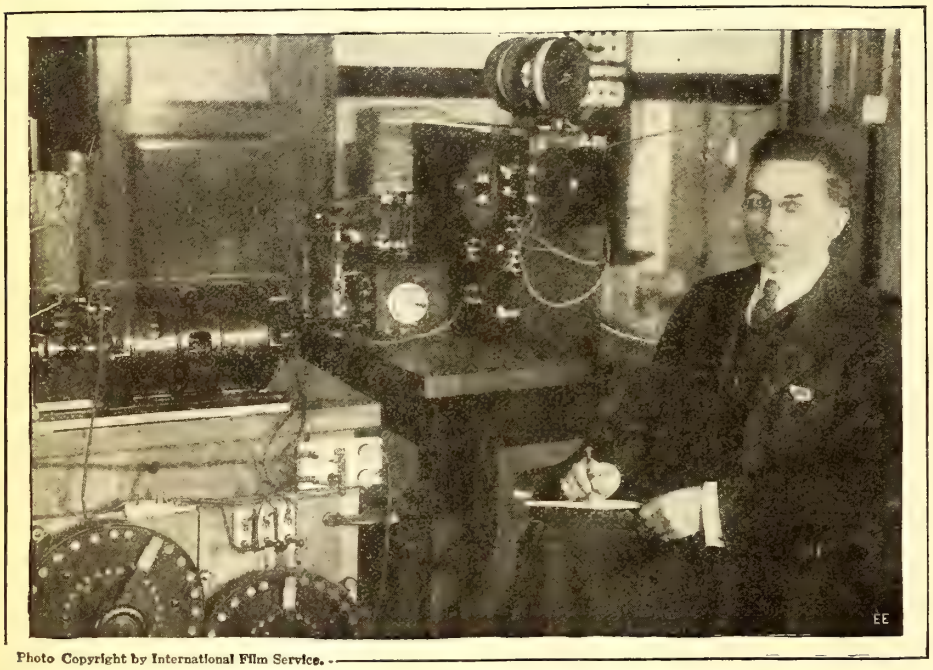

Photo Copyright by International Film Service.

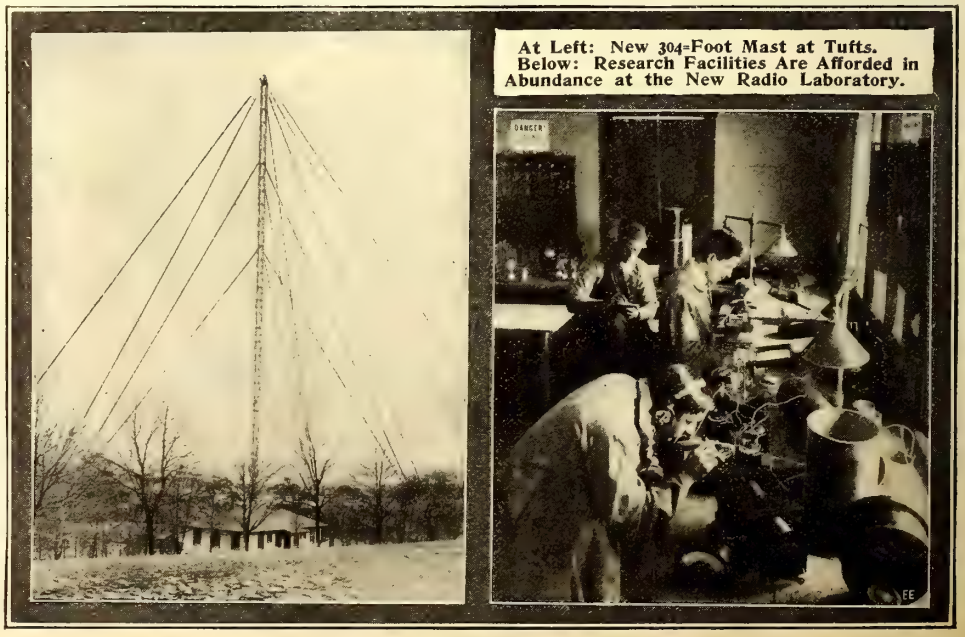
Frederick Kolster, of the U. S. Bureau of Standards, Inventor of New Radio Range and Direction Finder and the Apparatus Used.

Only vaguely and entirely by guess could a trained wireless operator tell by the strength or weakness of the "spark" the distance between himself and the instrument transmitting the call to which he was listening.

It has been left for one of the United State radio experts—Frederick Kolster, of the Bureau of Standards—to develop a satisfactory radio device of simple design, capable of ascertaining not only the *range*, but also the *direction* from which the wireless message emanated.



It is said that the device has proven very satisfactory in a number of careful tests conducted by the Bureau of Standards. Messages have been received on one or another of three different sizes of instruments that have been built so far—from Philadelphia, Boston, Glace Bay, Newcastle (N. B.), New York, Norfolk, New Orleans, Panama, Key West, San Diego and Hanover, Germany. This new device, perfected by Mr. Kolster, also cuts down the atmospheric disturbance effect noticeable in practically all other radio telegraphic receptors. The direction-finding apparatus of this inventor's design is operated entirely indoors, having no antenna and no earth or outside connection. Such a device is much in demand by radio inspectors and agents of the commercial radio companies for the purpose of checking up ship locations, interfering stations and the distances between ships, also between ships and lighthouses or fog signaling stations. Also it should find considerable application in the military service for field and trench work as receiving apparatus thoroughly portable, requiring no antenna or ground as aforementioned, is of light weight and can be readily carried by one man. Another distinctly useful application for it would be in the Coast Guard service in receiving distress signals, as they would be able to locate their source at once.

The photograph herewith shows Frederick Kolster, of the Bureau of Standards, and his new radio direction and range-finding apparatus.

TUFTS COLLEGE HAS NEW HIGH POWER RADIO STATION.

THERE has recently been completed and set in operation at Tufts College, Medford, Mass., a high-power radio station, one of the best equipped in the United States. The great feature of the station is the immense skeleton steel, aerial mast, 304 feet high, which is embedded in solid concrete. The new tower may be seen for miles, its slender black framework, only 3 feet 6 inches square at the base, silhouetted against the sky. The tower is supported on four specially designed porcelain insulators which are firmly secured in 15 tons of reinforced concrete. The mast is constructed of 12-foot sections of structural steel and is held in position by 12 heavy crucible steel guy wires, one inch in diameter, secured at different heights and embedded at their bases in blocks of concrete. The tower is topped by a huge antenna which extends outward like a monster open umbrella. This shaft is said to be the highest in New England and the third highest in the United States.

A few feet from the tower stands the laboratory building, also built of concrete. To the casual observer this solid looking structure has little significance. The expert, however, will find carefully housed there, a complete outfit of high-power wireless apparatus, machinery and tools of the

SENSITIVE MICRO-AMPERE WIRELESS RELAY.

It has been the dream of radio engineers for years that some day a relay would be perfected that would be sufficiently sensitive to respond to the extremely weak currents in circuits of wireless receiving sets, and we believe that the relay here described fills most of the requirements.

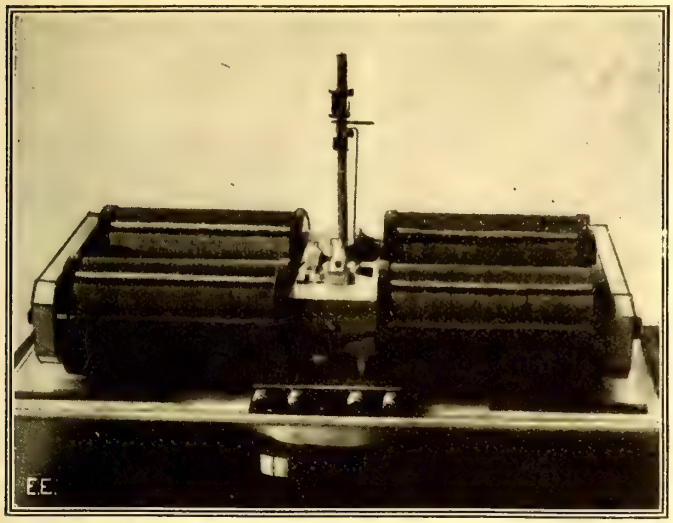

Fig. 1. A Wireless Relay That Operates on One-Millionth of an Ampere.

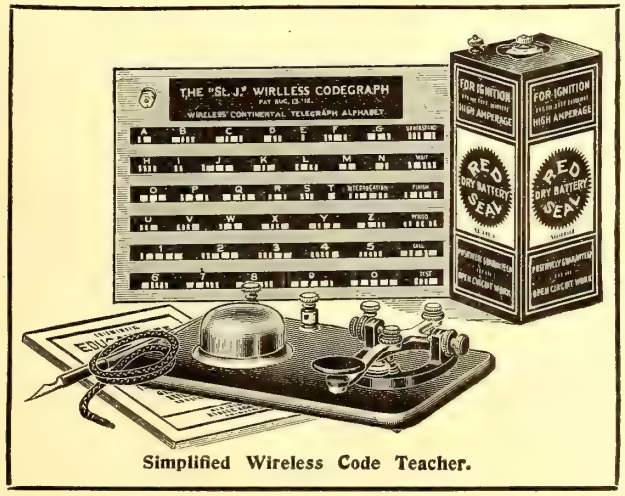
The apparatus as designed by Fritz Lowenstein, of New York, a well-known radio engineer, will operate on any receiving detector and is recognized as the most sensitive detecting device for electric current ever constructed for commercial use, as it will be deflected by a current of 1 micro-ampere (1 millionth of an ampere).

This super-sensitive relay is illustrated in Fig. 1, mounted complete on a stand, while Fig. 2 shows the details. The moving element C is wound with a coil of extremely fine wire and carries a contact D which makes connection with a small pool of mercury E when the armature is deflected. The moving part is supported on two-jewel bearings to eliminate friction and the connections to the moving coil consist of two very fine helical copper springs suspended at both ends. The upper spring is very clearly shown in Fig. 1. Two small discs F, F, are provided to regulate the swing of the coil, which is mounted between two pole pieces BB that are energized by the massive coils shown at A, A, A, A. The coils are so connected that the two pole pieces will have different polarities, thus forming a N. and S. pole. The current for these magnets is obtained from a 110 volt direct current supply and is led in through the wires G.

The operation of this wonderfully sensitive relay is as follows: The powerful electro-magnets are first excited and the moving coil is connected to the receiving outfit in place of the regular 'phones through terminals H, and a calling device, such as a bell, at the terminals I. When the coil C is excited by the feeble current produced by the detector, which, of course, is received by the other instruments from the radio transmitting station, it will turn, and its lever D will make contact with the pool of mercury E, thereby completing the circuit which causes the calling device to operate. The bell can be replaced with a tape register by which messages can be readily copied. This, of course, must be operated at a slow speed, as the moving coil has an oscillation period of .1 of a second. The oscillating frequency period can be changed by varying the distance of the levers F, F, and the coil. The ivory bone cup in which the mercury is kept can be moved either forward or backward by operating a small thumb screw located at the end of the container.

The complete relay is supported on a table that can be rotated to offset any detrimental effects of the earth's magnetic field. A suitable cover with a glass top is placed over the instrument to prevent any dust settling on the delicate moving parts. This device is capable of withstanding shocks and will work even when slightly tilted, for it has been tested on moving vessels and the results were very satisfactory.

Although the relay is adopted for radio work, it will be very useful in a laboratory where it is necessary to detect very minute or feeble currents. By mounting a sensitive microphone to make connection with the winding on the moving element this apparatus might then be used as a telephone relay, second only to the audion in sensitivity.



NEW WIRELESS CODE INSTRUCTOR.

A very simple wireless and telegraphic code instructor is that known as the "Mesco Codegraph." This outfit employs an enameled metallic plate, as perceived from the illustration, and on the face of which are arranged the dot and dash signals corresponding to the letters of the alphabet. The signal characters have the enamel left off them.

This little plate is connected up with a dry cell and ordinary buzzer, together with telegraph key. Ordinarily the Morse key shown is not used and the circuit is completed through the buzzer (or a sounder) by means of a steel pen, which is drawn across the bare metal dot and dash signals on the face of the metal plate.

These dots and dashes have the enamel scraped off, as explained, and thus a circuit is completed so as to give the proper sequence of signal characters. It is possible, of course, to thus learn the code without a teacher, and the speed may be varied as required, according to how fast the pen is drawn across the plate.

This neat little outfit should find a wide field of usefulness among the younger radio students who do not care to invest in a high priced instrument for the purpose.

Simplified Wireless Code Teacher.

PUPIN'S NEW NON-INTERFERENCE ANTENNA.

After giving an interesting discussion on the formation of electro-magnetic waves in the ether, with special regard to their adaptation in wireless telegraphy, Prof. M. I. Pupin, the well-known electrical engineer, discusses briefly the theory on which his new non-interference radio device operates, in *Science*.

In the elucidation of his theory Prof. Pupin goes on to say: "The eye sees a very narrow strip of wave frequencies which are sent from a radiating body; the ear hears but a very narrow strip of wave frequencies which vibrating bodies can send out. Physiological optics and physiological acoustics deal with these remarkable facts. Now, the reason why the eye is blind and the ear is deaf to an enormous range of frequencies is certainly not due to anything like ordinary selectivity produced by tuning.

"Fifteen years ago I published several investigations which deal with electrical motion in sectional wave conductors. One of these resulted in the now well-known loaded telephone line. I regret that the technical importance of this invention, by attracting too much attention, has overshadowed completely the full meaning of the general mathematical theory which underlies it. This theory says that sectional wave conductors (presumably in the form of inductance coils) can be made which will absorb almost completely all waves above or below a certain small range of frequencies, and the selectivity thus obtained has nothing to do with ordinary electrical tuning. In other words, the selectivity of the eye and of the ear can be imitated by coarse structures like sectional wave conductors. Electrical pulses produced by the static are for the most part very short and their action is equivalent to the action of highly damped electrical oscillations of very high pitch. This action can be entirely absorbed so that no part of it reaches the receiving apparatus of a wireless receiving station if between the antenna and the receiving apparatus a sectional wave conductor is employed which will not transmit electrical waves of a fre-

Electrical Losses in Radio Transmitting and Receiving Sets

By James L. Green.

PART I.

THE TRANSMITTING SET.

THIS article endeavors to deal with radio power losses and their prevention. The design and construction of commercial radio apparatus is now rec-

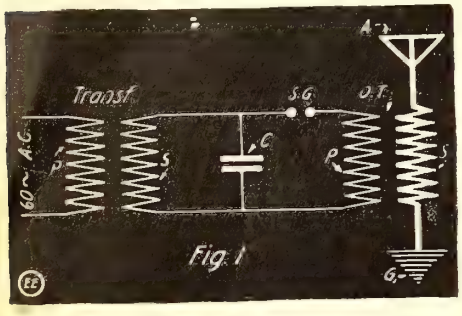

Fig. 1. Typical Radio Transmitting Circuit.

ognized as an important branch of engineering, and great care must be exercised so that the set will operate with the greatest all-around efficiency.

This requires that the electrical power losses be kept at a minimum and a maximum amount of energy radiated or received for a given input of power.

The equipment of a wireless station may be divided into two parts: 1. Sending set. 2. Receiving set.

Let us first consider the sending set: Take the average one-half kilowatt amateur set shown diagrammatically in Fig. 1, and consider the apparatus from left to right.

A. Sending Key.—The average amateur wireless key usually consists of an ordinary telegraph key with heavy contacts. Since the losses in a key are usually those due to heating of contacts and formation of oxides, dirt, etc., upon their faces, these may, by the use of *large studs,* be reduced until they are negligible. Other losses, i. e., at bearings may occur if these are allowed to work loose or become dirty or covered with oxides.

B. The Transformer.—For a full treatise on transformer losses the reader had best consult an engineering text-book on alternating current machinery. However, the more serious transformer losses are:

1. Conductor Loss.—Whenever a current traverses a conductor heat is developed. The amount of loss due to this heat is given by $W = C^2 \times R$, where W = loss in watts, C = current in amperes, and R = resistance of conductor in ohms. The copper loss is due to heating of the windings; and, to make this as small as possible, large wire must be used. There is, however, a limit to the size of wire used, as too large a wire makes the transformer bulky and thereby increases iron losses. For this reason transformers are nearly always designed with a certain copper loss—about 5 to 8 per cent.

Suppose now we wished to know the primary resistance for a transformer whose input = 440 watts and whose copper loss is 5 per cent. Then we can calculate the resistance for the primary of a transformer which on 110 takes four amperes.

From	$W = C^2R$
We get	$22 = 4^2R$
Whence	$R = 1.375$

Therefore, the primary resistance may be as high as 1.375 ohms for an allowable copper loss of 5 per cent.

In general the primary resistance of the amateur's transformer is less than this, so it is probable that the conductor losses of the ordinary amateur transformer are quite low.

2. Core Loss.—The iron losses in transformer cores may be divided into two classes: viz., hysteresis and eddy currents.

a. Hysteresis Loss.—When iron is subjected to the action of a magnetic field produced by an alternating current its polarity will change with every reversal of the current. To this change of polarity the iron offers a resistance. The lag in responding to such a change produces heat and is known as *hysteresis.* This hysteresis loss is small in soft iron and increases with the hardness of the iron. It may be reduced by using very soft transformer iron and by keeping the volume of the iron small.

b. Eddy Currents.—Since a conductor placed in a varying magnetic field has a current induced in it the iron in a transformer core, being subjected to an alternating current magnetic field, has currents induced in it. These currents are known as Eddy or Foucault currents, and run crosswise through the core. Hence, to minimize them, we can make the core of thin laminations of iron, insulated from each other.

In commercial practise the laminations are treated with acetic acid for a few hours until a thin film of rust forms over them. This has one advantage over shellac, which is often used by the amateur, as no amount of heating can burn or melt it. In the ordinary amateur type transformer, if built of transformer iron, insulated as described, and used on 60-cycle A. C., the loss due to hysteresis may not be more than 5 to 8 per cent. of the input.

3. Condenser Losses.—The losses in a high tension condenser are of two kinds.

a. Hysteresis.—Since the two plates of a charged condenser contain opposite charges, i. e., one positive, the other negative, and as these plates are separated by a dielectric there is always a strain across the dielectric, due to the attraction of the two charges. This strain is known as an electrostatic strain. If the charging current be alternating, then the strain will be first in one direction, then in the other. The dielectric will display an effect similar to magnetic hysteresis; i. e., it objects to the change of direction of strain. This reluctance causes power loss and is known as *dielectric hysteresis* and its energy is expended in heat. The amount of hysteresis loss in a condenser varies with the material used in the dielectric. It is dependent on: 1. Chemical composition of the dielectric. 2. Temperature. It is very small in air condensers and those having transformer oil, or flint glass as dielectric and quite large for ebonite or micanite.

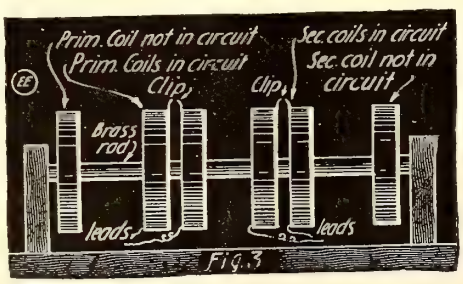

Fig. 3. Suggested Form of Loose Coupler Employing "Unit" Inductances Instead of Sliders or Switches.

b. Brush Discharge.—The *coronas,* or discharges of light, that issue from a highly charged conductor are known as *brush discharges.* They are most frequently noticed at sharp points or edges, and a portion of the charge is often thus lost in the air. This discharge is often noticed in antennæ and inductances, and is a particularly serious form of loss; for, besides part of the charge being lost in the surrounding conducting layer of air, the capacity of the circuit will be changed and thus the set will be put out of resonance. To overcome brush discharge

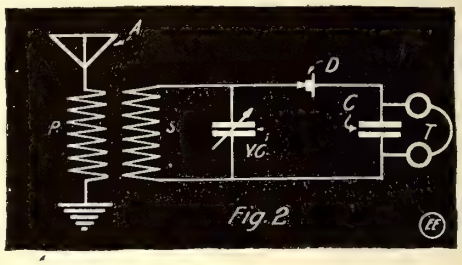

Fig. 2. Regular Wireless Receiving Circuit for Loose Coupled Tuner.

the condenser should have few, if any, sharp edges and should be of the oil-immersed type.

4. Spark Gap.—The losses in the spark gap are due to: a. Heating. b. Rapidity of quenching. The losses due to heating are usually small in the amateur set and, so far as these are concerned, almost any form of gap can be used. The quenching of a gap is determined by:

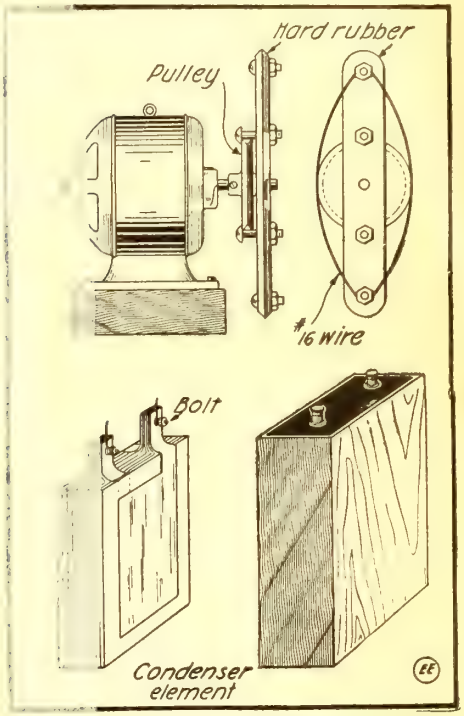
1. Material of gap. (Copper gaps quench most rapidly.) 2. Gas in which spark takes place. (Hydrogen and illuminating gas produce best results.) 3. Separation of the electrodes. (The gaps should not be closer than .01 inch. The spark should take place in an airtight chamber and the gaps provided with radiating flanges for cooling. In the larger gaps air blasts or water circulation systems are used to facilitate cooling.)

5. Oscillation Transformers.—These coils are really air-core transformers and serve the purpose of transferring the energy of the closed condenser circuit to the open antenna circuit. The preferred type of this transformer takes the form of two concentric, cylindrical coils wound with copper ribbon. It has been shown that by using a rapidly quenching gap and close coupling, a gain of 25 to 40 per cent. over the spark sets is readily possible.

6. Antenna.—The antenna losses may be due to:

a. High Frequency Resistance.—Since the currents in the antenna are of fairly high frequency the aerial should be of stranded wire, thus providing the greatest possible surface for the conductors used. The lead-in should be composed of a cable of the same wire as used in the antenna; the number of them being the same as in the aerial. This method should be followed in all cases.

b. Induction in Neighboring Masses of Metal.—Guy wires are very liable to give trouble in this direction unless broken up into short lengths by means of insulators.



c. Leakage Through Faulty Insulators.—This form of loss is only too well known and can only be remedied by using better insulators.

d. Brush Discharge from Aerial.—This form of loss was referred to under "Condenser Losses." It may be avoided by having no sharp ends or bends in the aerial wires and by having the "open" end of the antenna heavily insulated (since the voltage is higher at the farther end of the antenna). Use curved joints in all parts of the antenna, not square bends.

e. High Resistance Ground.—This is a

AMALGAM RECIPES.

Tin and mercury combine readily at or- temperatures. If 3 parts mercury ght into contact with 1 of tin 6- rystals of tin amalgam are formed. algam is used for silvering looking glasses. When pulverized and rubbed on the polishing stone it forms a kind of mosaic silver. Electric amalgam may be made by melting tin and zinc together in various proportions in a porcelain crucible. The xture is well stirred up, and when on the point of solidifying the mercury is added and worked into the mass. The which is next transferred to a mortar enough to keep the amalgam soft, it is well worked together, after a piece of tallow or lard, not quite n bulk to the mass, is kneaded in the amalgam attains the proper con- y.

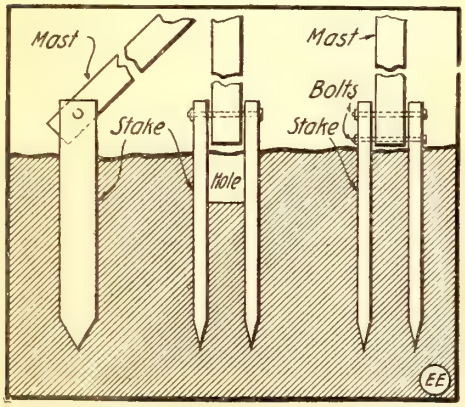
HIGH TENSION LEAD-OUT.

This lead-out terminal post is intended for use on radio transformers and condensers, but, of course, it may be used in any other place as a high tension bushing. It consists of hard rubber tubing 1½ inches in diameter and with a ¼-inch wall. The drawing needs little explanation. The dimension A should be whatever the diameter

Hard Rubber Tube Forms Efficient Lead-Out Insulator.

of the hard rubber is, in this case 1½ inches. The short piece should be one-half of the length of the outside one. The hard rubber tubing should be machined as per drawing, and the binding post and outside brass washer should be nickel-plated.

The brass rod should be threaded into the end of the binding post and fitted with two hexagon nuts and a spring washer. The rod should be of such length as to tightly clamp the hard rubber pieces as shown. In the assembled drawing is seen the lead-out complete, mounted presumably in a condenser or transformer base.



This insulator is easily made, is highly efficient and will add a "commercial" touch to any amateur equipment.

HOW TO ERECT AN AERIAL MAST.

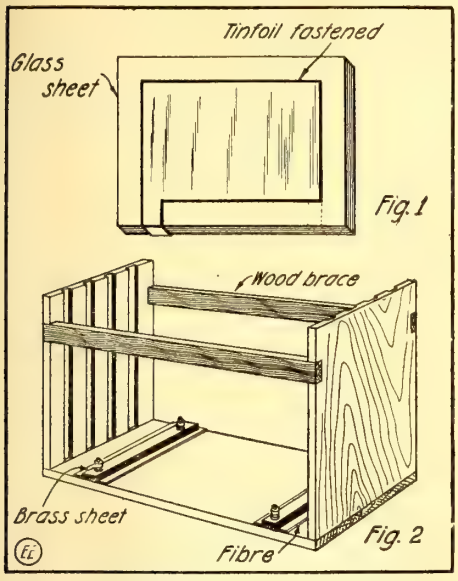
Many amateurs have great difficulty in raising an aerial mast. The method here described practically eliminates all difficulty.

Drive two five-foot wooden stakes into

Erecting an Aerial Mast.

the ground so that but one foot of each projects. The space between the stakes should be a little more than the thickness of the mast. Then dig a hole, in which the mast is to be placed when erected, between the two stakes. Drill half inch holes in both stakes as well as in the

QUEEN DECORATES WIRELESS OPERATOR.



Arthur Hankin, a former Trempealeau, Minn., boy, who until a few months ago was a wireless operator aboard a British warship in the Far East, is convalescing in a hospital in England after a long illness. Writing from the hospital, he tells how he was recently decorated by Queen Mary with a slip of heather. He says:

"I had the pleasure of shaking hands with King George of England and Queen Mary. Also, they both wished me a speedy recovery. The king and the queen arrived at the hospital early in the day and we were lined up to receive them. They came to each of us and shook our hands and asked about our experiences and where we had been stationed.

"The queen's lady-in-waiting had a bundle of white heather, and the queen handed each officer a piece, and she was kind enough to say she hoped it would be lucky to us."

TRANSMITTING CONDENSER CONSTRUCTION.

Below are shown details for constructing a useful and efficient form of the glass plate transmitting condenser for radio sets. The slide plates are readily remov-

Rack for Holding and Automatically Connecting Glass Condenser Plates.

able from the frame, as will be perceived, so as to make it of any capacity desired. Fig. 1 shows how the glass plates are coated on both sides with two tinfoil sheets. As is the usual plan, the lug from each sheet is carried down to the edge of the glass and passed across this edge in the manner shown. Now by glancing at Fig. 2 it is apparent how the alternating tinfoil on opposite sides of the glass plates are connected with the circuit at the plate edge as they are slipped into the frame, where the foil lugs rest on metallic strips at the base of the frame proper.

The frame itself may be constructed of wax-impregnated wood, or of fiber, hard rubber, etc. Photographic negatives make good condenser plates, as they are usually quite free from air holes. To remove the gelatine from the surface all that is necessary is to soak them in hot water for a few minutes, when the coating can be easily scraped off.

ALUMINUM WIRE FOR AERIALS.

My small antenna for 200-meter waves was composed of six No. 14 aluminum wires, fastened to heavy 17-foot spreaders. When it had been up about a month one of the wires broke at the spreader. A few days later another broke at the same point. This was followed by a break at one of the porcelain cleat insulators. Then I decided to make some changes. When I first fastened the wires to the spreaders and insulators I did it in the manner shown by Fig. 1 of the drawing. With copper wire no break would have occurred but aluminum wire cannot be bent many times without breaking it. The spreader, as it swung up and down in the wind, bent the wire, though slightly, at the point marked by the arrow. When I fastened the wires again I used the method shown at Fig. 2. I passed the wire around the spreader, or through the hole in the insulator twice and did not twist it as closely as in the first case. This left no sharp stop where the wire could bend. It also strengthened the wire at the point of greatest strain.

I also put on new spreaders of cypress one inch square and nine feet long. Cypress is strong, light and withstands the weather better than other woods. Later I took off two of the wires. When using four wires, instead of six, there is no difference in the strength of the signals in receiving. I am heard by other stations just as lou[illegible] too. The antenna worked no better with [illegible]ore wires spaced farther apart.

I found the lead-in wires were s[illegible] oxidized at the joints where the [illegible]a soaked through the tape—the join[illegible]

Method of Making Joints in Aluminum Wire Aerials.

not been soldered. In place of the tape I put on paraffined cloth. The cloth was simply run through the melted paraffin twice. After winding a few turns of wire around the cloth-covered joint I heated it with a match to remelt the paraffin inside. This made the joint watertight without the trouble that soldering entails. The aerial has been up five months without giving any trouble.

[NOTE.—On account of the above and similar troubles, aluminum wire for aerials is not used any longer in modern wireless stations, phosphor bronze, or the so-called "copper-clad" or "antenium" wire being used exclusively now. It is cheaper and better than aluminum.—EDITOR.]

[This is a fact not at once conceivable perhaps, but on reflection it is seen that if we do not tax the other senses, such as sight, that the sensitiveness of the ear is readily augmented.—EDITOR.]

TRUCTOR

d Construction of a Decremeter

Part II.—Conclusion

By Milton B. Sleeper

Assembling the Decremeter.

First fasten the coils in the case with the brass straps. Next, screw the parts on the front. See that the switch is in proper alignment with the pointer; make sure that the condenser plates do not touch; have the slider moving smoothly in the slot. No dimensions for the detector have been given, as any good model will do. The stand in Figs. 1 and 4 is of a very convenient design, however.

Fig. 10 shows how the connecting wires are run on the back of the hard-rubber panel. Use heavy, stranded, flexible rubber covered wire. *Small wires increase the damping of the instrument.* If the damping is too large the meter will be inaccurate. Leave enough wire on the switch connections, to allow the contacts to move freely. Before screwing the front to the case go over the connections; be sure that they are exactly right. With everything adjusted, the meter is ready for use.

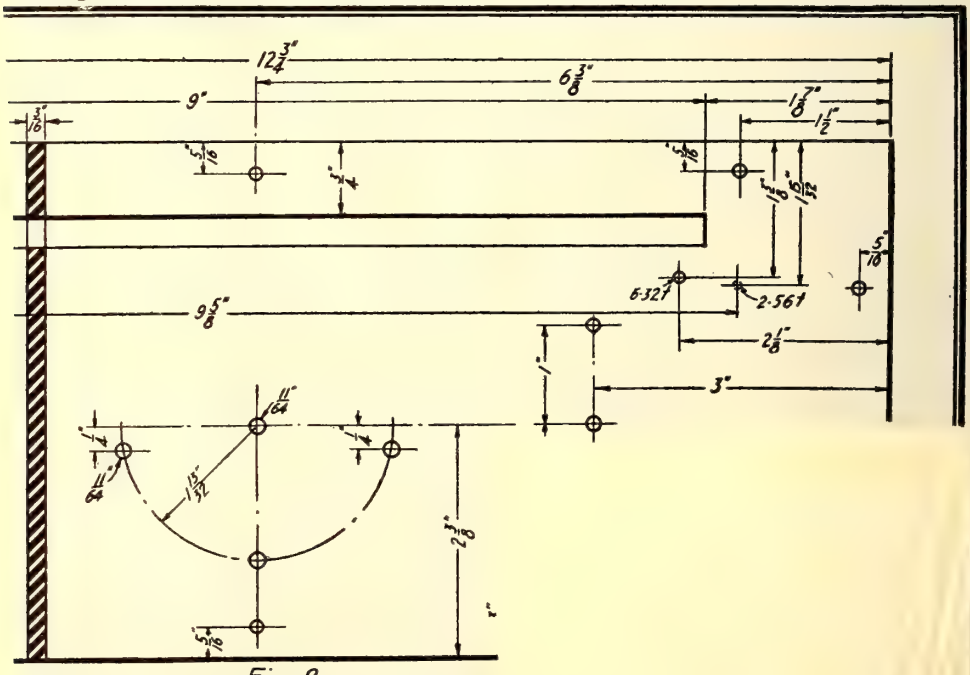

Fig. 8

of Decremeter Switch Panel, Showing Dimension

Use of the Decremeter.

Some understanding of the principles of the decremeter are necessary if the instrument is to be intelligently used. In Fig. 11 the circuit 1-2-3-4 resembles that of a decremeter as well as that of a wave meter. V. Bjerknes has proved that when this circuit is tuned to a transmitting set,

$$\delta = \pi\left(1 - \frac{\lambda}{\lambda_1}\right)\frac{1}{\sqrt{\left(\frac{n_1}{n}\right)^2 - 1}};$$

where:—

δ = decrement of the transmitter,

λ = wave length of the transmitter,

n = number of turns in 'phone circuit, when faint signals are heard,

λ_1 = wave length of circuit when it has been changed a small amount from that of the transmitter,

n_1 = number of turns in the 'phone circuit required to bring signals back to their former strength.

When the switch is in position 1, as indicated by the pointer, Fig. 1, or in position 3-4, of the back views, the small coil is in series with the long coil and condenser. The 'phone is connected across 26 turns of the long coil. Now, if the condenser is adjusted to put the circuit in resonance with the transmitter.

λ = wave length of the transmitter, and

$n = 26$ turns.

To summarize the operations in finding the decrement of a transmitter:—

1. Put the switch in position 1.
2. Place the meter about five feet from the helix.
3. Adjust the detector until sounds are heard in the 'phone when the key is pressed.
4. Turn the condenser until signals are loudest. *Do not touch the condenser again.*
5. Move the decremeter away from the transmitter until the signals are barely audible.
6. Change the switch to position 2.
7. Adjust the slider until the signals are *exactly* as loud as they were before the switch was changed.
8. The decrement of the transmitter will be indicated beneath the pointer on the scale.

Fig. 9. Details of Decremeter Case. To be made preferably of hard wood, well polished, such as mahogany or quarter-sawed oak. Three coats of shellac or varnish, each rubbed smooth with pulverized rottenstone and linseed oil, will yield a fine, glossy finish.

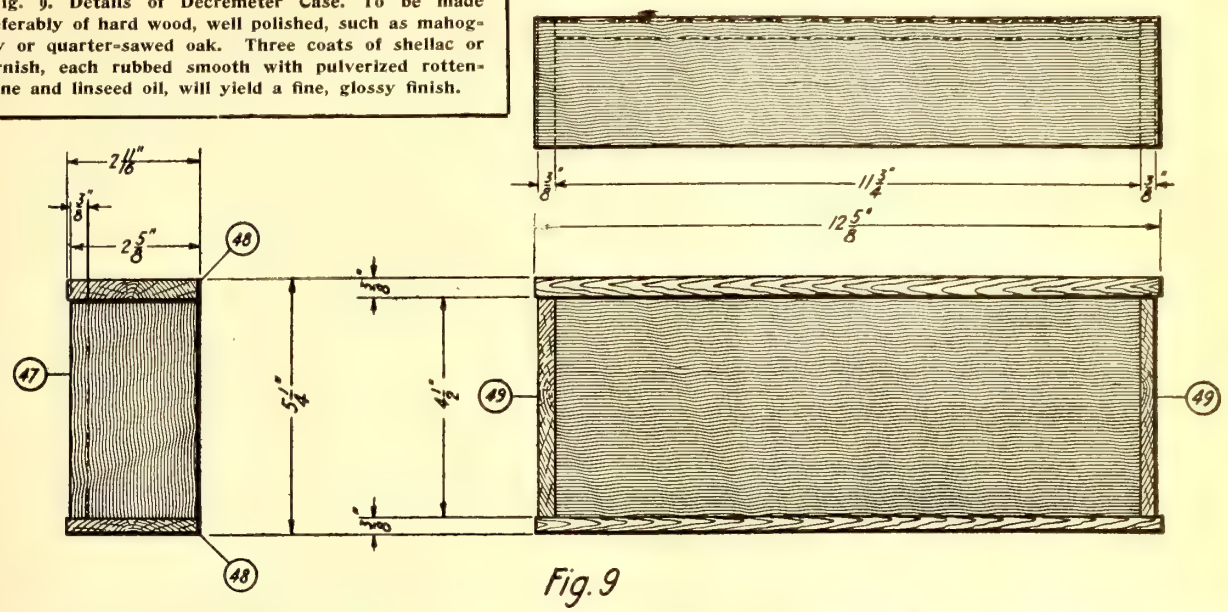

Fig. 9

Tuning a Transmitter with a Decremeter.

The decrementer can be used for a number of practical purposes. A decremeter can be used as a wave meter; the wave length being read from the condenser scale. In this case have the meter calibrated when the slider is at the extreme right and the switch in position 2. Always adjust it in this way when using it as a wave meter. Before measuring the decrement of a set always be sure that the wave lengths of the closed and open circuits are the same. If the meter is not calibrated to read as a wave meter it can still be used to bring the circuits into resonance. The method is as follows:—

1. Disconnect the antenna and ground from the oscillation transformer or helix.
2. Adjust the closed circuit for maximum efficiency with a hot wire ammeter or by the appearance of the spark.
3. Put the meter a few feet from the set. With the switch in position 2, adjust the slider roughly, and finally the condenser, for a maximum response in the 'phones when the key is pressed. *Do not change the slider again.* Note the reading of the condenser.
4. Connect the antenna and ground. Disconnect the closed circuit from the helix. In the ground lead insert a spark coil or buzzer to excite the antenna.
5. Adjust the clips until the maximum response in the 'phone is at the same position on the condenser scale as with the closed circuit. Now the two circuits will have the same wave length.

When the circuits are in resonance adjust the coupling until the hot wire ammeter in the antenna indicates a maximum radiation, or until the signals are heard loudest at a near-by station. At this point *measure the decrement.* If it is too large, separate the coils of the oscillation transformer, even though the radiation is decreased, until the decrement is 0.2. If the decrement is so high that it cannot be sufficiently reduced by loosening the coupling, without greatly reducing the radiation, there is something wrong with the construction of the set. The two circuits must be out of resonance, the resistance of the antenna must be too large, the ground connection poor, or the spark gap may be at fault. Any form of resistance in the antenna circuit will increase the decrement.

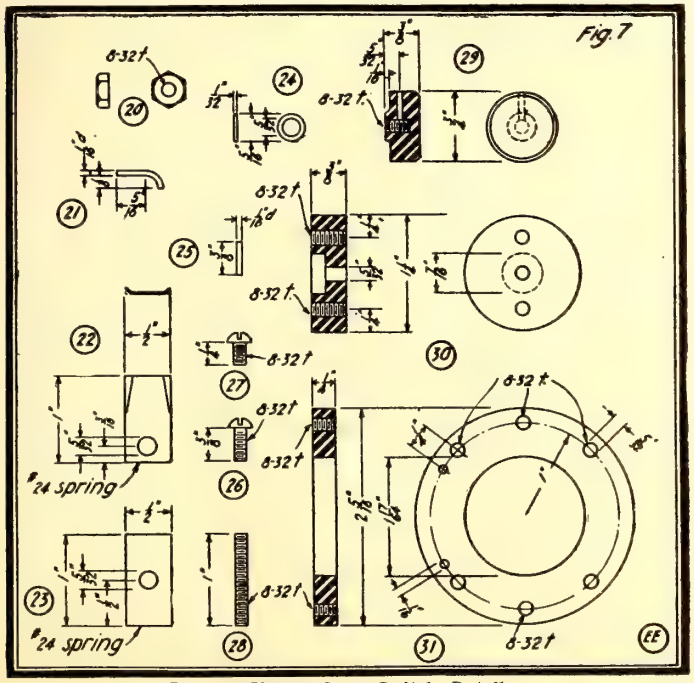

Fig. 7. Change-Over Switch Details.

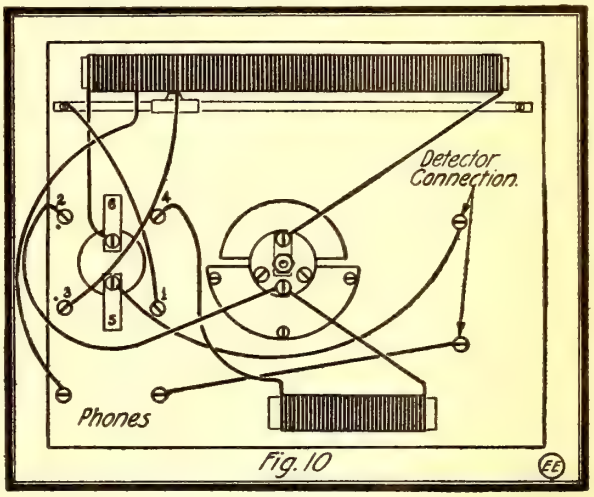

Fig. 10. How Parts of Decremeter Are Connected.

It is interesting and very useful to calibrate the decrement of the transmitter on a scale fitted to the oscillation transformer frame. If the station is equipped with a wave meter, the two radiated waves can be measured and set down beside each decrement reading. The decrement of a transmitter will change slightly in wet weather, or when the spark gap is changed. It is convenient, when calling a station to increase the decrement, or broaden the wave, by moving the coils of the oscillation transformer nearer together. This interfering wave will be heard by the station called, even though it is tuned to a wave higher than 200 meters. *After an acknowledgment has been received, reduce the decrement to the legal limit.* During interference the

decrement can be further reduced, if necessary, for the lower the decrement, the more sharply a station can be tuned at the receiving set.

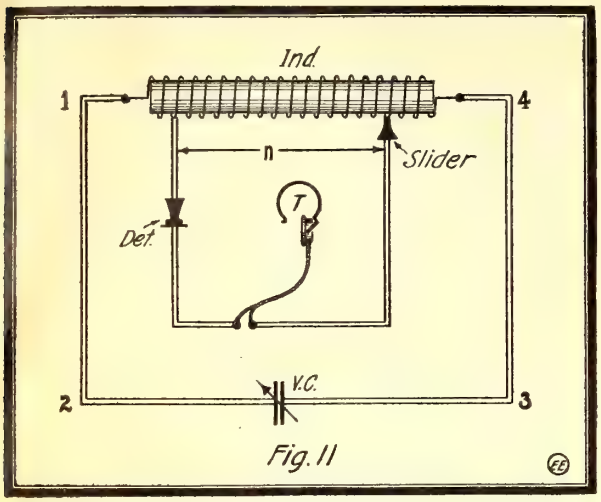

Fig. 11. Hook-up for Decremeter. (Schematic.)

If the decremeter is calibrated to read as a wave meter it is possible to plot a curve representing the tuning characteristics of the radiated wave in the following way: Put the switch in position 2. Adjust the condenser to a wave length below that of the transmitter, and move the slider to the left until the signals are barely audible in the 'phone, when the key is pressed. On a piece of cross-section paper measure up from the bottom a distance to represent the number of 1/100ths on the scale. Move the condenser to a position 10 meters higher. Again find out the number of turns required to make the signals just audible. Measure a distance to the right of the first line to represent the increase in wave length, and upward a distance to represent the number of scale divisions now indicated by the pointer on the slider. Plot a number of points in this manner, both above and below the wave length of the transmitter. Then connect these points by a smooth curve. If the decrement is small, and if the set can be sharply tuned at a receiving station, the curve will be quite sharply peaked.

The decremeter described in this article, particularly when calibrated as a wave meter, is one of the most useful pieces of auxiliary apparatus for any radio station. It is hoped that this description of the instrument will help to popularize the decremeter with experimenters by clearing up some of the points not understood about its construction and use.

AIR-INSULATED TESLA COIL.

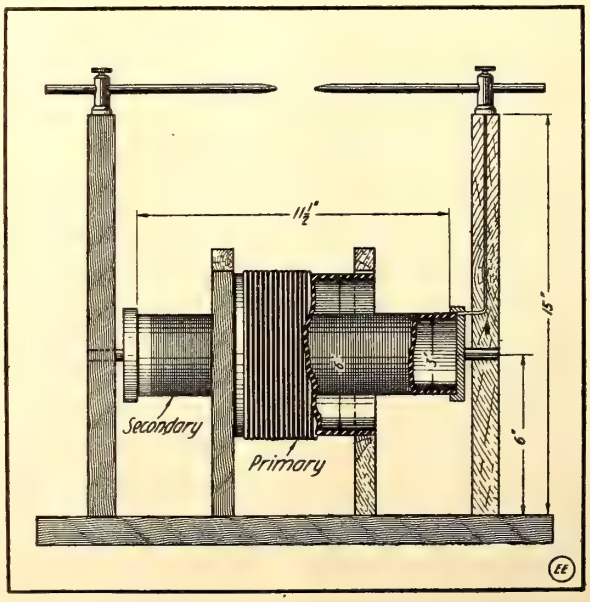
Experimenters who have wireless sending stations have all the apparatus necessary for the operation of an air-insulated Tesla coil.

The coil here described is suitable for use with spark coils giving from a 2-inch to 6-inch spark or with a ¼-kw. transformer.

The coil described in this article will give a 7½-inch spark when used in connection with a ¼-kw. closed core transformer (magnetic leakage type), glass plate condenser and a rotary spark gap. When a stationary gap is used the sparking distance is about 5 inches.

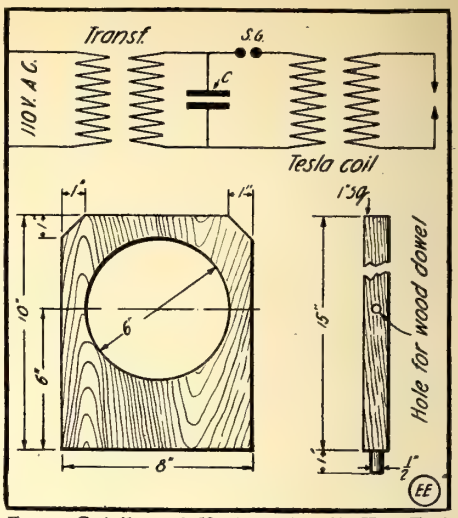
The illustration gives the necessary dimensions and shows part of the primary and secondard tubes cut away to bring out various points in the construction.

The primary consists of 21 turns of No. 14 B. & S. gauge rubber-insulated wire wound on a paper or fiber tube 6 inches outside diameter. This tube is easily made from a pasteboard box, which may be procured at any grocery store. This is also true of the secondary tube. The length of the primary tube is not shown in the illustration because there is a great variation in the thickness of the insulation of the different kinds of wire. There should be just enough space between the end pieces to accommodate 21 turns of the wire used. If No. 14 D. R. C. wire, which is almost ¼ inch in diameter, similar to that for electric light wiring, is used the space on the tube should be about 4 inches for 21 turns. This wire can usually be obtained, although stranded wire is preferable.



The secondary coil consists of one layer of No. 32 B. & S. gauge enameled or D. S. C. wire (cotton-covered may be used) wound on a tube 3 inches outside diameter. The winding should be 11½ inches long. The base and woodwork may be of any size the builder desires. The posts, however, must not be lower than indicated or the spark will jump into the primary winding.

The framework may be made of most any hardwood, or it can be made of poplar, but hard pine should not be used. The coil should be put together entirely with wooden dowels, because if nails or screws are used the sparks will jump into them.



The posts may be forced into half-inch or larger holes bored in the base to receive them and should be held with glue. The tubes may be fastened to the end pieces with glue, but it is preferable to fasten the larger tube into its end pieces by cutting a hole in each piece just large enough to allow the tube to slip into each end and fit snugly. See illustration showing the construction of these end pieces.

Holes may be bored in the base and in the end pieces to fasten them together with wooden dowels and glue. This is accomplished as easily as by using screws.

The next thing is to fasten the secondary into place. The best way to do this is to insert the two dowels projecting from the end of the secondary into the two holes bored in the upright posts to receive them and gently drive both posts into the holes made in the base for them. This completes the construction of the coil. The woodwork may be finished with any substance that is a *good* insulator.

Well Designed Tesla Coil. Will Give 7 to 8 Inch Spark When Used on ¼ Kw. Radio Transformer.

Frame Details and Hook-up for ¼ Kw. Tesla Coil.

The size of the condenser will depend upon the spark coil or transformer used and will have to be determined by the experimenter. For spark coils of about 2 inches a half-gallon Leyden jar may be used, but with larger coils the number of the jars should be increased until the correct capacity is obtained. This would also be true of plate condensers.

Very beautiful experiments may be performed with this coil in a dark room. The spark may be allowed to jump to a piece of metal held in the hand, but no sensation of pain will be experienced. If the spark jumps directly into the body only a slight burning sensation will be felt.

Lubricating oil may be placed on the end of the finger and lighted by means of the spark without burning the finger.

A very surprising and beautiful, as well as weird, effect may be produced by connecting small cotton-covered magnet wire, No. 32 or smaller, to each terminal of the secondary and leading them off to the side of the room, keeping the wires about a foot or two feet apart. It is, of course, understood that all Tesla experiments should be performed in absolute darkness, as the desired results may be obtained only in this way.

Another experiment is to ground one wire of the Tesla secondary and attach a piece of wire to the other secondary. This will cause an enormous brush effect on the free wire.

Scores of other equally interesting experiments may be carried on, but these the experimenter may easily find out for himself.

The writer will be pleased to hear from those who build this coil.

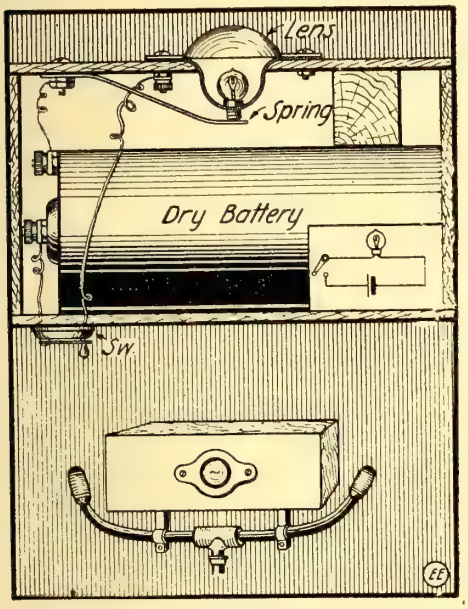
SOLDERING PASTE.



The materials required for making this very satisfactory soldering paste are a 15c. can of "Nokorode" flux, which is a brown substance, an old tooth paste tube or other collapsible tube and some solder. With a coarse file make an amount of solder filings equal to the flux and mix them together. Open the bottom of the collapsible tube and round out the flattened walls, being careful not to tear it. After cleaning it put in the mixture you have made and close the end. The paste may be squeezed out as required. Its action is similar to "Solder-all."

USEFUL BICYCLE HEAD LAMP.

This idea is original as far as I know, the light and battery being self-contained and mounted on the handle bars. I can imagine that this piece of apparatus will make quite a hit with those fellows owning an up-to-date bicycle built along motorcycle lines. I will not give dimensions as I believe each constructor will follow his own particular ideas. A box is constructed such that will give the battery a snug fit, so as to eliminate movement. A flashlight is procured, one of the pocket type. A very cheap flashlight will suit. Cut out the parts, as shown, the correct size and lines being left to the constructor. Mount this, as shown, on the proposed front of the box. A piece of spring metal connects the bottom contact of the lamp. A switch is mounted on the side nearest the rider, preferably one with removable blade such as the Keystone switch, so that no one will tamper with the light when the rider is otherwise occupied. The cover may be provided with hinges or screwed on. A block of wood wedges the battery in the case tight. Purchase from a bicycle supply store two frame pump holders, which will cost a few cents. Cut as shown and screw onto the box, mounting same on handle bars, as indicated. The diagrams, I think, are self explanatory.

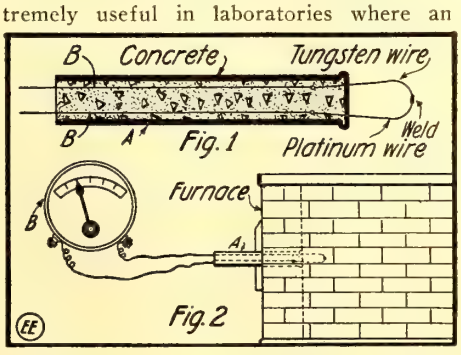
Bicycle Head Lamp Made to Use Standard Dry Cell.

HOW TO MAKE AN ELECTRIC THERMOMETER.

The experimenter who is intensely interested in general research work should not by any means miss an electric thermometer in his laboratory. The commercial thermometers of this class are very expensive, and this is one reason why the experimenter generally lacks such an instrument. The Pyrometer, as it is technically called, and herewith described, was built by the writer, who used it successfully in connection with an electric furnace developing 2,000 degrees Fahrenheit.



The detecting apparatus consists of a thermo-couple made especially for high temperature. The first thing is to obtain a short piece of No. 20 platinum wire about 2 inches long and a piece of tungsten wire of the same gauge and length. One end of each piece should be welded together to form a single long strip. This can be readily accomplished by splicing them together and heating to a bright redness in a Bunsen burner, or still better, in an oxy-acetylene gas burner. After this is done two long copper wires B B are next welded onto each end of the loop, Fig. 1. The welding is done in the some manner as with the other two wires, but care should be taken not to heat them too long, as the copper ones are apt to fuse on account of the low melting point of copper compared with tungsten and platinum. The wires are now placed in an 8-inch porcelain tube, which is then filled with a concrete mixture, or even better, with lime (calcium carbonate), saturated in water and allowed to dry. This mixture keeps the wires in place and at the same time will keep the interior wires from overheating during the use of this apparatus.

The recording device B, Fig. 2, consists of an ordinary milli-voltmeter with a scale calibrated in *degrees* instead of in millivolts. The scale should be removed and another scale without any figures or marks replaced. It is now ready to be calibrated. Both instruments should be connected as shown in Fig. 2. The detecting apparatus is placed in a furnace giving a temperature averaging about 200 to 300 degrees Centigrade; then carefully insert a standard mercury thermometer into the same furnace. The standard must read 300 or more degrees, as the temperature of the furnace will cause the mercury to reach its limit until it will force itself through the bulb, thus damaging the instrument. Read the scale on the mercury thermometer and note the deflection of the pointer on the milli-voltmeter scale. Mark off a point and, if possible, increase the temperature of the furnace and take another reading, marking another scale point. The figure obtained on the standard should be noted on the scale of the unknown. Marking these two points, the rest of the scale is equally divided and spaced according to the divisions previously found. It should read to 2,000 degrees.

For those who are not familiar with the operation of this instrument, a few words will suffice. Whenever any two dissimilar metals connected together are heated or cooled below the temperature surrounding these conductors a current of electricity is set up, which in turn registers on the millivoltmeter scale. The current produced by the thermo-couple is directly proportional to the heat produced by the furnace; therefore heating the two wires with a greater temperature produces a greater deflection on the indicating device, etc.

Having completed the outfit, the instrument is now ready for actual use. This electric thermometer will be found extremely useful in laboratories where an electric furnace is used for producing refractory substances and artificial gems.

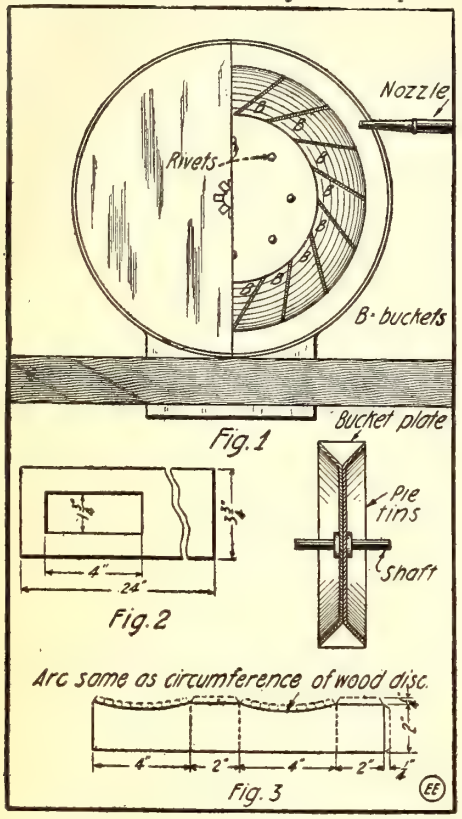
CLEANSING MERCURY BY WASHING.

While distillation under reduced pressure is the most satisfactory method of removing impurities from mercury, it is often sufficient to wash thoroughly with diluted nitric acid. As usually performed this is rather a mussy undertaking, but by means of the apparatus illustrated on this page the trouble is reduced to a minimum.

The washer consists of a mercury reservoir A and a tall glass tube B open at both ends, the capacity of the latter being several times that of the former. A three-way tap C is also required. Two of the side tubes D and E are bent upward and passed through an India-rubber cork F, closing the lower end of the large tube. To one of these is attached the glass tube G, which reaches almost to the top of the wide tube and is bent downward and drawn to a fine jet at the end. The other tube D should be flush with the cork. A length of pressure tube H makes a flexible connection between the reservoir and the tap.

Mercury Cleansing Scheme.

The soiled mercury having been placed in the reservoir A, and a quantity of diluted nitric acid in the wide tube B, the action proceeds as follows: Upon raising the reservoir to the position shown in the illustration and putting it in communication with the tube G by means of the three-way tap, a thin stream of mercury will pass through the column of acid, collecting at the bottom of the tube. The reservoir may then be lowered as far as it will go and the tap adjusted so that the mercury flows back through D. The operation should be repeated several times to insure thorough cleansing, the reservoir being supported in the upper and lower positions respectively by means of a wire cradle and hooks, or in any other convenient manner. The mercury should afterward be washed in clear water and dried by heating in a glass or porcelain basin to just above the boiling point of water. Contributed by



H. J. GRAY.

Don't test storage cells with an ammeter. It forms a complete short circuit and will eventually ruin the cells. Use a voltmeter. Don't use lighted matches to examine storage cells. The gas given off forms an explosive mixture.

Safety first—don't handle electric wires even though they are 'phone wires. They may have become crossed with a high voltage transmission line, which means instant death.

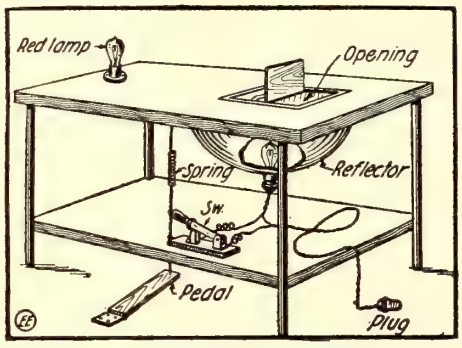
A HANDY HOME-MADE WATER MOTOR.

A very useful water motor that will run a small dynamo or a sewing machine on a pressure of about 30 pounds water pressure can be made at a very small expense.

A Home-Made Water Motor for Experimenters.

Procure two 7-inch flaring edge pie plates 1 inch deep. Find the exact center and punch a pin hole through the bottom of each plate. Place the plates with their bottoms together and hold their centers in line by placing a pin through the holes. Rivet the plates together, using eight rivets spaced equal distances apart on a circle 4 inches in diameter. Then solder the joint all the way around the plates.

Cut 16 triangular pieces of tin to fit between the edges of the plates (see sketch). Solder them at uniform intervals around the plates, between the diverging edges. These form the buckets and should be placed at an angle, as shown in Fig. 1.



After the buckets have been finished drill a ¼-inch hole through the center of the pie plates for the shaft. Slip a ¼-inch brass rod through the hole and solder it in place. *Be sure that the rod is perpendicular to the plane of the wheel.* The shaft should be at least 6 inches long. Solder a brass thrust collar ¼ inch thick and ⅝ inch from the bottom of the plates on the shaft. There should be one on each side of the wheel. Now saw out two round hard wood discs of wood ½ inch thick and 7½ inches in diameter. Boil them in paraffine to make them waterproof. Drill a hole through the center of each, just large enough to admit the bearing. The bearings are made of brass tubing having an inside diameter of ¼ inch. Take a piece 1 inch long and with a hack saw cut six slots in one end ⅜ inch deep. Then bend out the end of the tube at right angles to itself. Make two bearings in this way and fasten one in each wooden disc with screws. Next cut out a piece of tin 24 inches long by 3¾ inches wide In the center of same cut a hole 4 inches by 1¾ inches, as shown in Fig. 2.

Punch holes 1 inch apart and ¼ inch from the edge on each of the long sides. Wrap the tin around the edge of one of the wooden discs and tack it tightly in place. Then place a brass washer on each end of the shaft and put the wheel in place. Now slip on the other disc and tack the tin to it. Solder the place where the ends of the tin overlap. Next cut out a piece of tin the size and shape shown in Fig. 3 for the spillway. Fold the tin on the vertical dotted lines and solder the overlapping ends. Bend the edges at right angles and place the spillway over the bottom hole in the cylindrical casing. Solder it carefully in place. The nozzle is made of an oil-can spout, cut off so that the hole is about ¼ inch in diameter at the smaller end. Solder the spout to a hose connection. Now drill a hole in the center of the casing as in Fig. 1. Connect the nozzle to the faucet by means of a short length of hose and turn on the water. Ascertain the position of the nozzle where the maximum speed is obtained, then solder it firmly in place. Next cut off one end of the shaft close to the casing. Allow the other end to protrude far enough to hold the pulley. The pulley may be of the flat or "V" grooved type and can be fastened to the shaft with a wedge key or set screw. The pulley should not be over 2½ inches in diameter. Contributed by

KENNETH KRUGER.

A PRINTING TABLE FOR AMATEUR PHOTOGRAPHERS.

A very convenient printing table for the amateur photographer may be made as follows: Any table may be used, but one with

An All-Around Electrically Lighted Printing Table for Photographers.

a lower shelf between the four legs of the table is desirable. First cut a hole in the top of the table just large enough for the printing frame to slip in. Strips of thin wood are tacked to the under side of the table top, so that the printing frame rests upon them. A single-pole, single-throw knife switch is next mounted on the shelf underneath the table. To the blade of the switch is fastened one end of a coiled spring. (An old curtain spring will do). The other end of the spring is then fastened to the under side of the table top and adjusted so that the switch is normally open-circuited. A st.ing is then fastened to the handle of the switch blade and run through a small hole in the shelf to a suitable foot treadle made of wood. One end of the foot board is hinged to the floor and the other end is held a few inches above the floor by the string attached to the switch blade.

An incandescent lamp of the desired candlepower is stationed directly beneath the printing frame and about 10 inches from same. A good reflector, such as a tin basin, will add to the intensity of the light. It is best to white enamel the inside of the reflector. When the foot plate is depressed it closes the circuit through the switch and lights the lamp. Upon releasing the pressure on the treadle the spring causes the switch to become open-circuited, thus extinguishing the light. By means of this arrangement both hands are left free for the printing operations. A red lamp may be kept constantly burning over the table if desired. All connections are clearly shown in the diagram.

WALTER F. CURRENT.

USING MOTOR AS TRANSFORMER.

The experimenter finds himself oftentimes in need of a transformer to reduce the voltage of the ordinary alternating-current house lighting circuit down to a point where it can safely be used in connection with miniature lamps, bells, small motors and other apparatus. A bell transformer, which is a cheap enough instrument to buy and which, in fact, is quite readily made by anyone who is handy with tools, is just the thing for this purpose, but it sometimes happens that an instrument of the sort is wanted at a moment's notice, and a substitute would thus come in very handy. In such a case it is well to remember that an ordinary shunt wound, direct current fan motor, properly connected to the alternating-current lighting circuit, will serve the purpose of a transformer. Of course it is not as efficient as a device which is wound expressly for the purpose of stepping down the lighting circuit voltage, but nevertheless it can be used and therein lies its chief virtue.

For the purpose it is necessary to use the field circuit of the fan motor as the primary of the transformer. To do this, disconnect the field entirely from the armature circuit and hook it up to the lighting current, as plainly indicated in our illustration. Hook up the apparatus to be run by the low voltage to the brush terminals and it will be found that, with the lighting circuit on, an alternating current at about six volts—it depends a whole lot on the winding of the motor—can be taken from the armature of the fan motor. It is possible to alter the potential of the transformer current slightly by shifting one of the brushes on the commutator, so as to include two or more coils. It is not well to try the experiment with a series wound motor, since neither the resistance nor the inductance in the field of the series motor will be found sufficient to prevent short-circuiting of the house current. Contributed by E. F. HALLOCK.

Using a Small Motor as an A. C. Step-Down Transformer.

USEFUL TELEPHONE HOOK-UPS.

The telephone circuits which are described in this article are those being regularly used by a large telephone manufacturing company and they will undoubtedly prove of value to the young electrician.

Figs. 1 and 2 show two party systems,

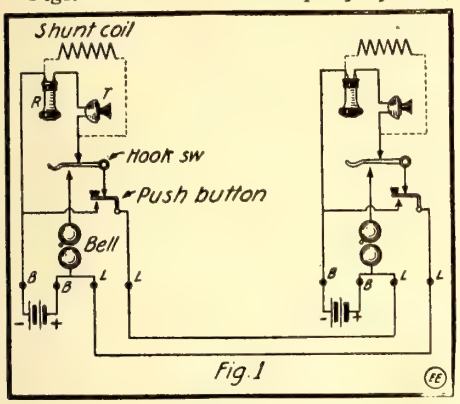

Fig. 1. Hook-up for Plain Series Telephone Set.

one employing two line wires and two sets of batteries and the other utilizing three line wires and but one set of batteries, located at any convenient point between the terminals BB. In case it is desired to use no "call" push button on either of these systems a shunt coil (a small coil of wire) can be bridged across the transmitter and receiver as indicated; its resistance depending on the resistance of the bells. Apparently the transmitter and receiver is short-circuited, but this is not so. When using shunt coils simply connect as shown by the dotted lines and omit the push buttons.

Fig. 3 shows a method by which three to six 'phones can be used on four wires. Inasmuch as all bells ring in multiple, they should be of about the same resistance. Special "code" signals are generally used to call the desired party. Talking is also in multiple, so an impedance coil must be used. An impedance coil is nothing more or less than an electromagnet, in this case being about 14 ohms resistance and is used to keep the direct current from backing up out of the receivers.

The diagram at Fig. 4 depicts a common (multiple) talking, selective ringing cir-

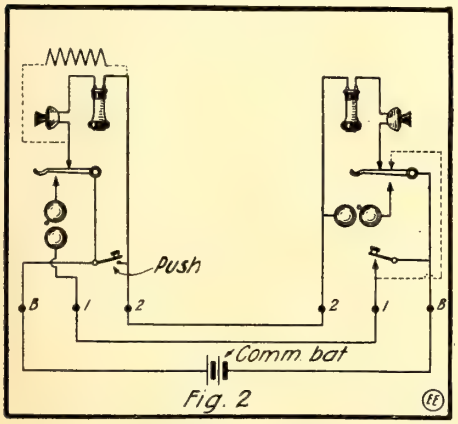

Fig. 2. Simple Battery Telephone System Utilizing Three Wires.

cuit, in which an impedance coil is also used. Any number of telephones can be used on this system, but only one pair at a time. There are always three more wires than telephones and one section wire for each, which must be connected as shown.

The above are about all the connections for which any amateur electrician would find any use, but there are scores of others which would dazzle the eyes of many a young "hope."

In conclusion let me say that wherever a battery call system is used no induction coil is needed, as any direct current that can be used to ring a bell can most certainly be used for talking.

THE CHEMISTRY OF THE STORAGE BATTERY.

In a brochure issued by the Titan Storage Battery Co., prepared by W. E. Winship, Ph.D., the chemistry of the lead storage battery is well expressed in brief, as follows: The active materials of the lead storage battery, spongy lead and lead peroxide, together with the sulphuric acid and the water of the electrolyte, enter directly into the chemical reaction which takes place on charge and discharge of the battery. (Note particularly that it is chemical energy that is stored in the battery and not electricity as such.)

On discharge, the spongy lead and lead peroxide are converted into lead sulphate at the expense of some of the sulphuric

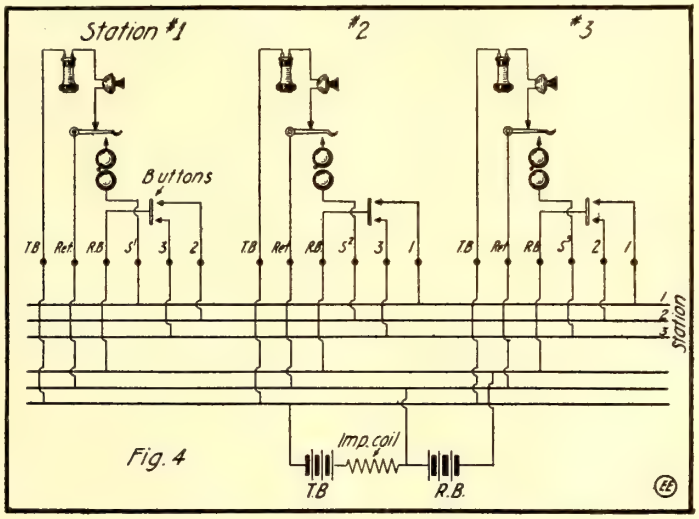

Fig. 4. Common Talking, Selective Ringing Telephone Hook-up.

acid, and in an amount almost exactly proportional to the ampere-hours discharge; while in addition some water is formed, which dilutes and decreases the specific gravity of the electrolyte. The original chemical energy is decreased by an amount equal to the electrical and heat energies developed, the latter being relatively small.

On charge the reverse action takes place, the lead sulphate previously formed on discharge being converted back to spongy lead in the negative plates, and to lead peroxide in the positive plates, a certain amount of water being chemically combined, in again forming the sulphuric acid and lead peroxide.

The lead storage battery, therefore, belongs to that class of batteries which are more or less reversible in their action. It is not completely reversible because of the heat generated and because of other actions described below.

The chemical reactions taking place may be expressed by the following equations:

Reaction at Positive Plate.—(*a*) $PbO_2 + H_2SO_4 = PbSO_4 + H_2O + O$.

Reaction at Negative Plate.—(*b*) $Pb + H_2SO_4 = PbSO_4 + 2H$.

Combined Reaction at Positive and Negative Plates.—(*c*) $PbO_2 + Pb + 2H_2SO_4 = 2PbSO_4 + 2H_2O$.

H ..... Hydrogen
H_2O ..... Water
H_2SO_4 ..... Sulphuric Acid
Pb ..... Spongy Lead
PbO_2 ..... Lead Peroxide

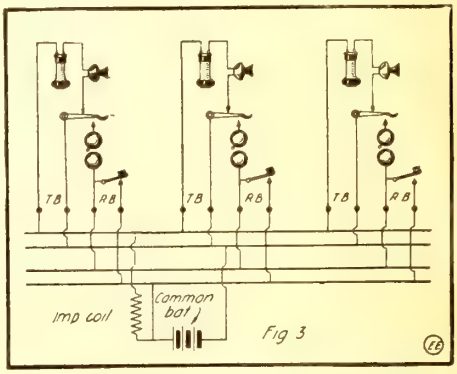

Fig. 3. Multiple Telephone System Using Common Talking and Ringing Wires.

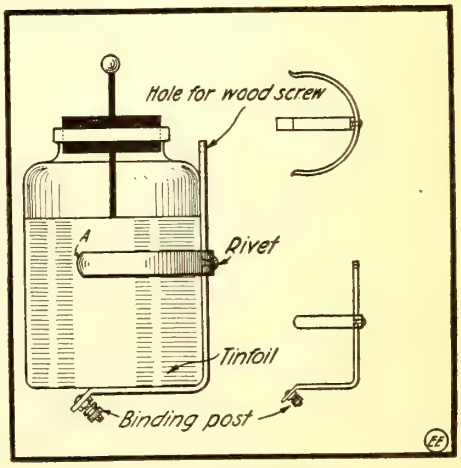
$PbSO_4$ ..... Lead Sulphate
O ..... Oxygen

These equations are the fundamental equations of the lead storage battery.



Equation (*c*), read from left to right, is the equation of discharge, and shows the change of spongy lead and lead peroxide on the negative and positive leads, respectively, into lead sulphate and the formation of water from hydrogen and oxygen of the electrolyte. Reading from right to left shows the reactions during charge.

The above reactions are those which normally take place. If impurities are present

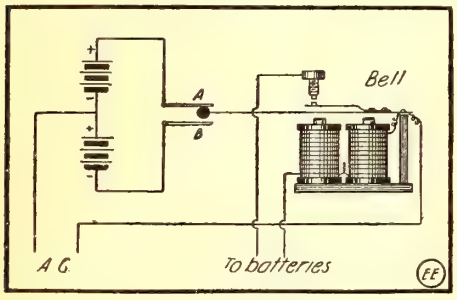
HOW TO MAKE IT



This department will award the following monthly prizes: FIRST PRIZE, $3.00; SECOND PRIZE, $2.00; THIRD PRIZE, $1.00.
The idea of this department is to accomplish new things with old apparatus or old material, and for the most useful, practical and original idea submitted to the Editors of this department, a monthly series of prizes will be awarded. For the best ideas submitted a prize of $3.00 will be given; for the second best idea a $2.00 prize, and for the third best a prize of $1.00. The article need not be very elaborate, and rough sketches are sufficient. We will make the mechanical drawings.

FIRST PRIZE $3.00.

A SIMPLE A. C. CONVERTER.

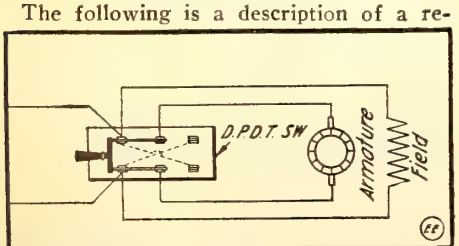
For performing certain electrical experiments, or in operating certain electrical instruments, such as the Poulsen wireless tikker, telephone bell ringers, etc., it is necessary to use an alternating current.

The instrument here described is quite simple in construction, yet capable of con-

An A. C. Generator Constructed from Ordinary Bell.

verting a direct current into an alternating current (of square wave form) of quite high frequency if properly adjusted.

First procure an electric bell, remove the gong and straighten out the clapper, then fasten it upon a suitable base. Two thin brass strips A and B are now fastened in position, one on either side of the clapper, as illustrated. One brass strip connects to the positive terminal of one set of batteries, while the other brass strip connects to the negative terminal of another set of batteries. These contact strips should be quite close together so that the time interval taken for the striker arm to pass from one contact to the other will be short.



By referring to the wiring diagram it is understood that upon starting the bell the clapper will vibrate from A to B, causing the current to surge first from one set of batteries, then from the other; causing a direct current to be converted into an alternating current.

SECOND PRIZE $2.00.

A SIMPLE CIRCUIT TESTER.

The materials required for making this "tester" are a piece of zinc, a piece of blotter and a piece of copper, together with a set of telephone receivers, preferably of about 2,000 ohms resistance.

The dimensions of the zinc, copper and blotter sheets are optional with the builder, but I found that if the pieces are made an inch square the current developed in the battery will be sufficient for ordinary testing purposes. In making the battery it is best to solder a piece of wire onto the copper and zinc before assembling. It is assembled as follows: First saturate the blotter thoroughly with a 20 per cent. solution of chloride of zinc, next place the zinc square on one side of the blotter and the copper square on the other, and finally press the whole together. The battery is now completed, but its life will be prolonged if it is covered with paraffine to keep out the air.

When in use, one of the leads from the battery is attached to one of the tips of a set of 'phones; then if the other tip and terminal are attached to a *closed* circuit a loud click will be heard, but if the circuit is *open* there will be no sound. The "tester,"

Handy Testing Outfit Utilizing 'Phone and Blotter Battery.

if properly made, will save much time and temper in ascertaining whether a circuit is closed or open.

Chloride of zinc is used because it is hygroscopic, i. e., it attracts water, thereby keeping moist for a long time. Besides, chloride of zinc does not attack zinc on open circuit.

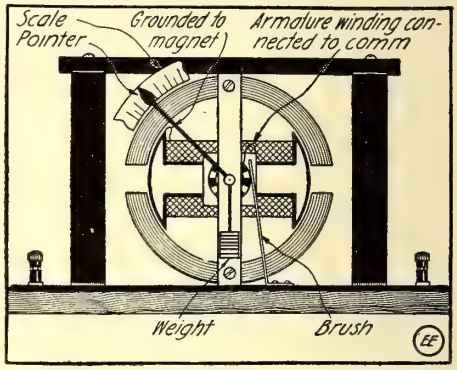
J. WALLACE PECKHAM.

A STATIC TRICK.

Static electricity around moving belts in some plants is so pronounced that it is necessary to provide special means for carrying it to the ground.



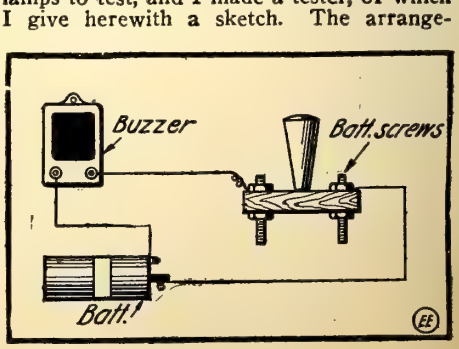
The following is an amusing trick: Hold the base of an electric light bulb close to a moving belt which is generating static. Now approach the innocent victim and offer him the lamp, of course extending the base. The moment he touches the base he will receive a surprise in the nature of a harmless shock. The explanation is simple. The lamp acts as a condenser, the hand holding it being one plate and the filament the other.

Contributed by C. REX GILBERT.

THIRD PRIZE $1.00.

A MOVABLE CORE AMMETER.

This ammeter acts on the principle of the D'Arsonval instruments. An ordinary, permanent steel field magnet motor, of the type illustrated, is used. All that is necessary is to remove one connection and one brush from the commutator; then bind a



Converting a Small Motor Into an Ammeter.

wire around the latter to make it a conducting ring. Ground the connection which was removed to one of the magnet pillars, then connect the pillar to one binding post. The commutator is connected to the other. A weight on an arm is soldered to one projecting end of the shaft, as also a pointer. This latter is made by hammering flat a piece of No. 18 copper wire at one end; now cut the flattened part to a sharp point. A suitable scale is placed on the instrument which is calibrated by comparison with a standard ammeter.

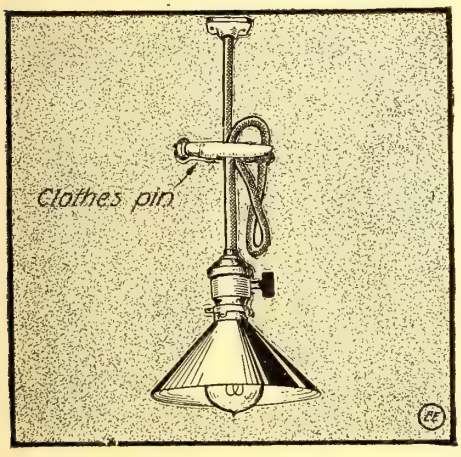
CONVERTING OIL BICYCLE LAMP INTO ELECTRIC.

This is a description of an electric bicycle lamp made from an oil type lamp, as shown in the accompanying sketch.

The materials required are an old



Converting Oil Bicycle Lamp Into Electric.

"Solar" lamp or any oil or gas lamp like that in sketch, a single point switch S W, flashlight batteries B, a miniature socket S, 2.5-volt bulb and some insulated wire. First remove the old burner from lamp, then remove the three small cells from the flashlight battery and cut the case to fit the cells; solder connections to the cells and place them in the bottom of the lamp. Mount the switch on top of lamp and fasten socket to the reflector R. Put the bulb in socket and connect up, as shown in diagram, and lamp is ready for use. It can be used as a bicycle lamp, or, also, it proves handy as a flashlight.

Contributed by CLIFF PINKERTON.

CLOTHES-PIN LAMP CORD ADJUSTER.

Many times, when working in a basement or other place, the electric lamp is in the way, and when a regular cord adjuster is not handy it is very troublesome to have to tie the lamp cord in a knot. The accompanying illustration shows a method that can always be resorted to. The holder shown is a common wood clothes-pin which holds the cord very

A Clothes-Pin Serves as a Lamp Cord Adjuster.

nicely in any desired position.

Contributed by WALTER FRANSEEN.

WIRE AND SHEET-METAL GAUGES.

There are at least eight wire and sheet-metal gauges in use in the United States at the present time, and this gives rise to much confusion and misunderstanding among those not conversant with their use. The following are the principal gauges:

Birmingham or Stubs' iron wire gauges.
American or Brown & Sharp gauge.
Roebling's and Washburn & Moon's gauge.
Stubs' steel wire gauge.
British Imperial Standard wire gauge. (Legal standard in Great Britain since March 1, 1884.)
United States Standard gauge for sheet and plateiron and steel. (Legal standard in the United States since 1893, used in determining duties and taxes.)
Morse drill and steel wire gauge.
Edison or circular mil wire gauge used in electrical work.

These gauges have letters or numbers to correspond to the different sizes of wire or sheet-metal, but as these numbers do not correspond in actual measurement in the different systems, there is likely to be misunderstanding if care is not taken to designate which gauge you are using in making your measurement.

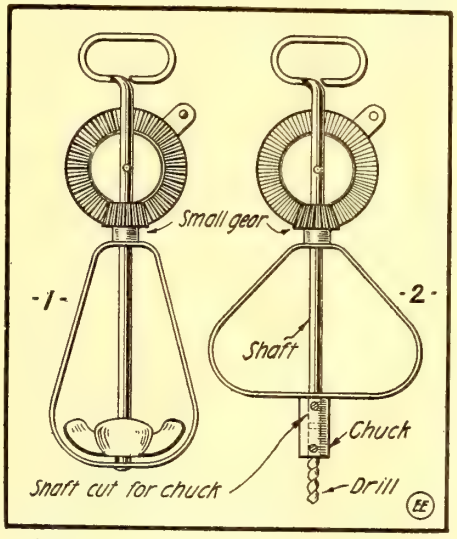
Take any number at random, say No. 5, and it has the following values for diameters or thickness on the different gauges reading in decimals of an inch, .22, .18194, .207, .204, .212, .219, .205; and No. 5 on the Edison gauge would be 70.72 mils diameter for electric wire.

The above comparisons are enough to show the necessity for care in the use of wire and sheet-metal gauges. If you wish to get from the dealer just the size of wire you want, and you have a gauge at hand which corresponds to the size, be sure and name the kind of gauge, as for example, "No. 5 measured by American or Brown & Sharp gauge."

If you have no gauge but have some of the wire such as you want, send the dealer a sample with your order.

If you attempt to measure the wire or sheet-metal with such instruments as you have at hand you probably will have difficulty in doing so as some of the sizes have no variation until the fourth decimal place is reached.—*Gas Review.*

STORING CHEMICALS.



The chemicals used in connection with electrical experiments are for the most part perfectly safe if handled with ordinary care. Acids should always be kept in glass stoppered bottles, since corks are rapidly eaten away to the detriment of the acid, as well as the cork. Dry crystals that are not deliquescent, that is, not absorbing moisture from the air, may be kept in cardboard boxes. Preserve or fruit jars often come in handy for the same purpose.

Deliquescent salts should be kept in glass bottles with wide mouths. Corked bottles that are not likely to be opened for some weeks or months may be made perfectly air tight by dipping the cork for a moment in melted paraffin wax contained in a shallow tin.

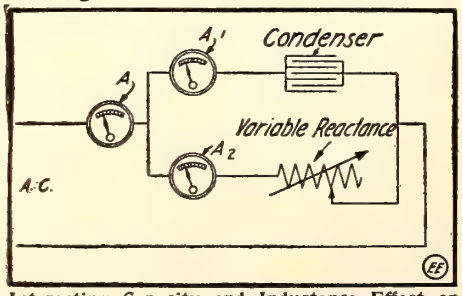
AUTOMATIC ELECTRIC DOOR SWITCH.

Many electrical experimenters have lighting circuits for illuminating dark closets and sometimes forget to turn off the battery when through with it, with the result that the batteries and light soon become worn out. They will probably find a ready use for this device of mine, which never "forgets," as it works automatically.

As can be seen from the drawings, when

Automatic Closet Switch Extinguishes Lamp When Door Is Closed.

the door of the closet is open (there being no pressure on the button) the brass strips come into contact, thus closing the circuit. The reverse is the case, however, when the door is closed. Thus opening and closing the door makes and breaks the circuit, respectively.



To make the switch cut or saw a piece of dry wood into the shape shown at A. Then bend and fasten on it two springy brass strips B, with two screws and nuts, which serve the double purpose of holding the strips in place and acting as binding screws for battery wires. A cross piece C, with a hole in the middle for button, is then screwed or glued into position. Care should be taken that the button connects with the under brass strip and not the upper, as this is the important feature of the device. Lower figure shows he switch screwed in position on the top jamb. If a neat appearance is desired cover with shellac or varnish.

Contributed by JOHN T. DWYER.

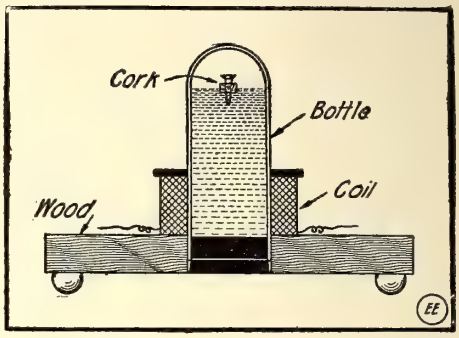
AN INTERESTING A.C. EXPERIMENT.

The following is a very interesting experiment in electrical phenomena, which will undoubtedly interest some of your readers, and those who are interested in wireless already have the necessary apparatus for performing this experiment at hand.

A condenser and a variable reactance are connected in multiple with ammeters A, A_1 and A_2, as shown in diagram. The reactance should be varied until ammeter A has reached its maximum reading; such a condition is called electrical resonance. It will be noted that the sum of the readings A_1 and A_2 will be very much greater than A, which is apparently contrary to the laws which govern a divided circuit, as the am-

Interesting Capacity and Inductance Effect on A. C. Circuits.

meters indicate that more current is flowing in the divided circuits than is actually entering them. The theory for the above can be found in any reputable text book on alternating currents under the head of electric resonance.



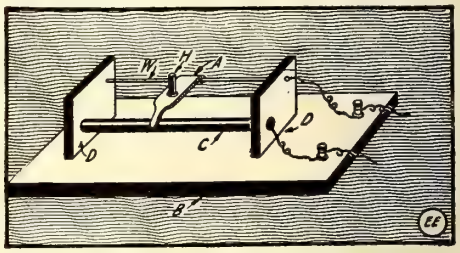
This experiment, when carefully reasoned out, should prove very amazing as well as instructive to the embryo electrician.

Contributed by H. C. YEATON.

AN EFFICIENT BATTERY TESTER.

This battery tester, although it does not tell the exact number of volts and amperes in a battery, will tell roughly the amount of energy left in it.

Procure a piece of wood 2½ inches square and ½ inch thick and put a ⅛-inch bevel on it. Then find the center of it and bore a ⅝-inch hole. Procure a small straight bottle, such as cheap colognes come in, and fasten it securely in the hole



The Magnet Coil Attracts the Cork and Iron Screw, Forming a Useful Battery Gauge.

by wrapping paper around it and gluing it so that the neck of the bottle is flush with the bottom of the wood. Glue a cardboard disc in the center of the bottle and let it dry securely. Then take a ⅞-inch wire nail and a small bit of cork. File off the nail and cut the cork so that there is *just* enough cork to float the nail in water. Then measure off about 20 feet of No. 20 magnet wire and wind it between the wood and the disc of cardboard so as to form an electro-magnet. Next fill the bottle with water and after dipping the cork in shellac, seal the bottle. By putting one wire on the carbon and the other on the zinc, the cork will go down and will rise as soon as the power is shut off. The harder and faster it goes down, the more current the battery contains. On a very weak battery it will simply move on the surface.

Compound Coffee (for Dispensing).—8 oz. best (ground) *Java Coffee;* 2 drm. sliced *Vanilla Bean;* add diluted *Alcohol* in sufficient quantity.

Plain Coffee Extract.—Pour upon 1 lb. of best fresh roasted *Coffee* 1 qt. of *Cold Water,* heat gently for half an hour then let it come to a boil, cool for 2 hours, strain and add 4 oz. of *Glycerine.*

Ginger (for dispensing).—Take 1½ pt. of *Fluid Extract of Ginger,* 3 pts. of *Water,* 3 oz. of *Carbonate of Magnesia;* mix, shake often for 24 hours; filter, evaporate to ¾ pt. and add ¾ pt. of *Alcohol.*

Mead.—Oil of Lemon, 1 oz.; *Oil of Cloves,* 2 drm.; *Oil of Cinnamon,* 2 drm.; *Oil of Nutmeg,* 1 drm.; *Oil of Allspice,* 30 drops; *Oil of Sassafrass,* 40 drops; *Oil of Ginger,* 1 drm.

Cut the *Oils* with *Pumice* and *Sugar;* dissolve in 16 or 32 oz. of *Alcohol.*

Add gradually an equal quantity of *Water;* clarify.

Liebig's Meat Extract.—1 oz. *Lean Meat,* very fresh, chopped very small; add 8 oz. *Cold Water;* shake well together for 10 minutes; heat gradually to boiling, let simmer gently for a few minutes, strain through a hair sieve while still hot; evaporate to a soft substance.

Sarsaparilla Extract.—Take 16 oz. *Jamaica Sarsaparilla,* cut transversely, 280 oz. *Distilled Water* (160° F.), macerate in half the water for 6 hours and decant the liquor. Digest the residue in the remainder of the water for six hours more, mix the liquors, press and filter.

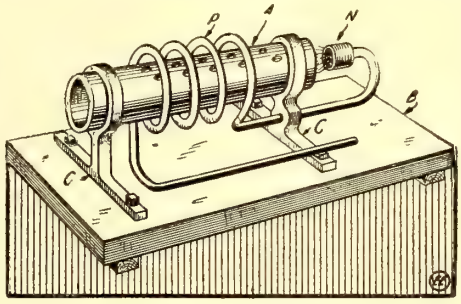
Evaporate by a water bath to 7 oz. when cold, add 1 oz. of *Rectified Spirit.*

Peach.—3 drm. *Oil of Almonds,* 3 drm *Oil of Pineapple,* 3 drm. *Tartaric Acid,* 1½ pt. of *Alcohol,* 80°.

Pineapple.—2 oz. of *Pineapple Essence,* 1 oz. of *Citric Acid,* 2 pts. of *Alcohol,* 80°.

Strawberry.—1½ oz. of *Pineapple Oil,* ¾ oz. of *Tincture of Orris,* ¾ oz. of *Tartaric Acid,* 1½ pts. of *Alcohol,* 80°.

S. G.



Did you ever stop to think that for every carbon lamp in your chandelier you may have three times the candlepower at the same cost for current by substituting tungsten lamps.

When you think of a new idea, write it down. Otherwise you will forget it.

A GASOLINE TORCH FOR THE EXPERIMENTER.

A very handy gasoline torch for the experimenter's laboratory can be successfully and easily built. This torch will develop a considerable amount of heat, which is frequently needed for certain experiments. The burner is made from a piece of brass tube, A, as illustrated in illustration. This should be ½ inch in diameter and 2½ inches long, plugged up at both ends, one end being drilled and reamed out to 5-16 inch. Three rows of holes 1-16 inch in diameter are next drilled in the tube as depicted. One row is drilled to come directly on top and the other two at about 45° from the vertical. It is then fitted to a sheet steel base, B, by means of the clips, C, C. A piece of ⅛-inch copper pipe, P, is next coiled around the brass tube, A, to form the vaporizing coil. This coil should have a diameter of about 1 inch. One end of the copper tube is bent around so it will point directly into the reamed out hole in the end of the brass tube, A. A nipple, N, is made by drilling a ⅛-inch hole half way through a piece of brass, topped to fit the ⅛-inch hole. A 1-64-inch hole is then drilled through the remaining part of the nipple. The other end of the copper tube is connected to the supply tank.

The distance between the nipple, N, and the end of the tube, A, should be only 5-16 inch. The supply tank can be made from a brass tube 3 inches in diameter and 6 inches long, with the ends sealed by soldering on two end pieces of the same material. A small cock is provided, which is directly connected to the torch. A small

A Home-Made Gasoline Torch.

hole is made on the top of the tank to allow air entering the interior, in order to force the gasoline to the burner. Care should be taken in handling the gasoline, as it is very inflammable. It will be found that the torch will produce a hotter flame when the copper coil is quite hot; this is due to the fact that the gasoline is more readily vaporized and consequently a better mixture is produced.

In order to start this device vaporizing it is necessary at first to warm the coil by means of a match, or with a little gasoline ignited under the worm.

Contributed by LOUIS WEISS.

CHEMICAL EXPERIMENTS.

By W. A. Talmage.

THE POPULAR WINE AND WATER TRICK.

OBTAIN a small quantity of phenolphthalein from your chemist or druggist in powder form. Dissolve it in a small bottle and keep well corked. When ready for the trick (before the performance) place some of this solution in a small crystal or porcelain pitcher and partly fill with clear water, then prepare four wine glasses or small tumblers as follows: No. 1 glass with about a teaspoonful of ammonia. No. 2 glass clear. No. 3 glass with a teaspoonful of ammonia, and No. 4 glass with two teaspoonfuls of acetic acid.

More glasses and chemicals may be used if desired, but must be prepared as above. To perform the trick pour from pitcher into glass No. 1 and we have *wine,* then into glass No. 2 we have *water,* and glass No. 3 we have *wine,* then glass No. 4 we have *water;* pour back glasses 1, 2 and 3 into pitcher and then fill the three glasses with *wine* from the pitcher, now pour all four glasses back and then fill them with *water* from the pitcher.

A little practise before you attempt this with your friends will enable you to handle glasses and pitcher skilfully. Try to cover the solution in glass No. 4 with your hand when pouring into it for the first time.

CHEMICAL COLOR CHANGES.

The following chemicals should be dissolved separately in individual bottles, labeled properly and kept tightly corked:

No. 1—Permanganate of potash, ½ dram; water, 4 ounces.

No. 2—Caustic soda or potash, 1 dram; water 4 ounces.

No. 3—Hyposulphite of soda (hypo), 2 drams; water, 4 ounces.

No. 4—Bichloride of mercury (poison), ½ dram; water, 2 ounces.

(Be sure and label bottle *poison.*)

No. 5—Sulphate of iron, ½ ounce; water, 4 ounces.

No. 6—Red prussiate potash, ½ dram; water, 2 ounces.

No. 7—Oil of tartar, this is made as follows: Carbonate of soda or common washing soda, ½ ounce; water, 4 ounces.

No. 8—Acetic acid (clear acid).

The above chemicals are all used in photography and may be purchased of any photo dealer.

In a tumbler containing a small quantity of water place enough No. 1 solution to give a nice wine color, then add about a half teaspoonful of No. 2 solution, this will slightly redden the No. 1 solution; now place a few drops of No. 3 solution, this will change to green; add a small quantity of No. 8, you will observe this to turn brown and then clear itself. Rinse tumbler out thoroughly.

Put about ten drops of No. 4 in half tumbler water, add a small quantity of No. 7, this changes to a deep orange color; now add a small quantity of No. 8, immediately clears itself. Remember that No. 4 is *poison* and should be handled with extreme care. Rinse glass thoroughly.

A small quantity of No. 5 in a half tumbler of water will be a clear solution and a small quantity of No. 6 in half tumbler of water will be clear; add both together and you will have a deep navy blue.

By further experimenting with above chemicals you will be able to perform many other changes.

MYSTERIOUS SMOKE TRICK.

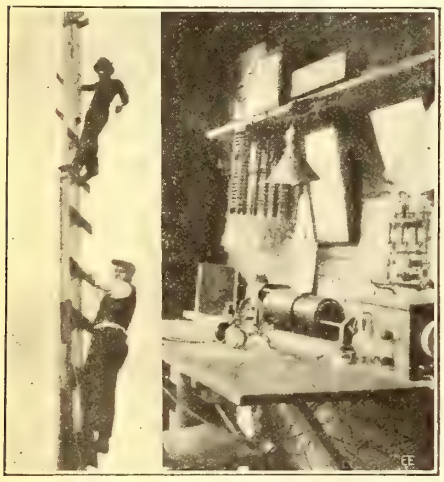
Place a small quantity of ammonia in a tumbler and upon a small piece of clear glass place a few drops of muriatic acid. Tell one of your friends that you can find out whether he is an excessive smoker or not, and have him place his thumb on the under side of the sheet glass and carefully turn it over on top of the tumbler with his thumb still in position; the result will be an excessive amount of smoke issuing apparently from his thumb.

MYSTERIOUS FIRE.

A small quantity of chlorate of potash mixed with the same amount of sugar placed on a piece of tin or stone and then touched with a stick dipped in sulphuric acid will instantly burst into a bright white flame. If a small quantity of strontium nitrate is mixed with this the flame will be red instead of white, or if the same amount of barium nitrate is mixed instead of strontium the flame will be green.

WITH THE AMATEURS

Our Amateur Radio Station Contest is open to all readers, whether subscribers or not. The photos are judged for best arrangement and efficiency of the apparatus. To increase the interest of this department we make it a rule not to publish photos of stations unaccompanied by that of the owner. Dark photos preferred to light toned ones. We pay each month $3.00 prize for the best photo. Make your description brief. Address the Editor.



AMATEUR RADIO STATION CONTEST.

Monthly Prize, $3.00.

This month's prize winner.

C. HERSCHEL WOODRUFF'S RADIO STATION.

A short time ago a ½-K. W. "Hytone Set" was left in my care with permission to use it on my aerial. I tried a little experiment which cleared up the trouble. This is the method to follow: First, take a piece of lamp cord, which is made of a number of small wires, and ground the earth side of the oscillation transformer. Then make a small gap of about ½ inch, using one strand of the lamp cord as one electrode. At first you may get a heavy, thick spark when the key is pressed, which

Lower Figure on Mast Is C. H. Woodruff, Owner of Station Shown at Right.

would not melt the wire, but by changing the tuning you will be able to get a spark which will melt a No. 10 copper wire.

With this arrangement I was able to "raise" a dozen amateurs. The range covered Cincinnati, St. Marys, Lima, Tiffin, Mt. Gilead, Mt. Vernon, Springfield and Fort Wayne, Ind. (9.P.C.).

The aerial was 90 feet long, 4 wires spaced 2 feet apart, 65 feet high. In the picture of my mast, the lower figure is myself, while the one above is a friend of mine (8.T.T.). The transmitter is ¼ K. W. with oil condenser, rotary gap and oscillation transformer. The gap is enclosed in a box just above the oscillation transformer.

The receiving set is of my own construction, as is the transmitter, and consists of 4,000 meter loose coupler, audion detector and 'phones. My set is capable of sending 40 miles and covers from 25 to 35 miles regularly. The receiving outfit has a range which covers Tampa, Fla., Miami, Fla., Key West, Galveston, Texas and Port Arthur.

C. HERSCHEL WOODRUFF.

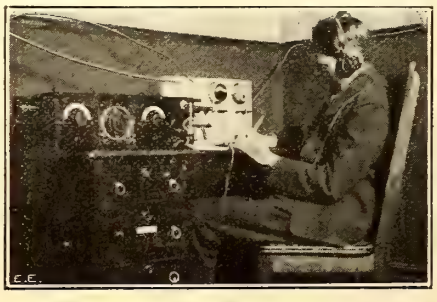
Columbus, O.

HAROLD BENNETT'S RADIO STATION.

Herewith I present a description and photograph of my wireless station for competition in your Amateur Wireless Station

Wireless Station of Harold Bennett.

contest. All of my instruments were purchased and mounted in cabinets. On the left of the illustration will be observed the receiving set, which is composed of an Arlington type D transformer, and detector (on top of cabinet). On the side of the case is a loading coil, variable fixed condenser and receiver block. My receivers are 2,000-ohm type of the Murdock make. The sending set consists of a spark coil used in connection with a separate interrupter and condenser. On top of the cabinet is a spark gap and a large helix.



I can transmit 13 miles and receive 1,500 miles, hearing Arlington and several other high-power stations. I would be glad to hear from any amateurs, or exchange photographs of my set with them.

Clarinda, Ia. HAROLD BENNETT.

LONG DISTANCE RADIO STATION OF C. L. TODD.

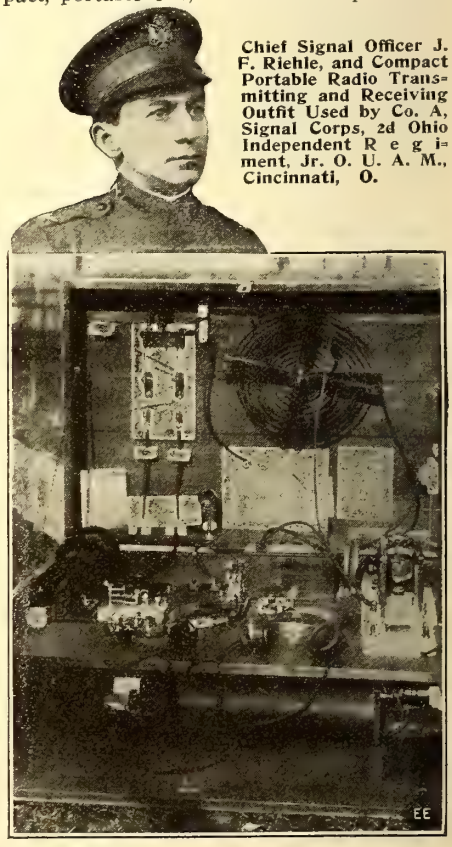
Herewith is a photograph of my radio station, the description of which is as follows: The transmitter consists of a "Blitzen" ½-K. W. transformer with Clapp-Eastham condenser, Murdock rotary gap and a "jigger" (oscillation transformer). Sending range approximately 300 miles. QRK at 2CE and QSA at 8LQ. Marble switchboard contains meters and antenna switch.

The receptor is mounted in and on a mahogany cabinet fitted with hard rubber

Conway L. Todd Receiving Radio Messages.

face. The instruments contained thereon are: Two Clapp-Eastham "Cambridge" variable condensers, their type "D" tuner, De Forest audion and loading inductances controlled by telephone cam switches. Receiving range about 2,500 miles.

The antenna is triangular, 30 feet on a side, constructed of stranded phosphor-bronze wire No. 10. It is 50 feet in height and very well insulated.



I would be glad to hear from any amateur within range. Working hours from 7 to 11 p. m. Call 8 A. D. E.

CONWAY L. TODD.

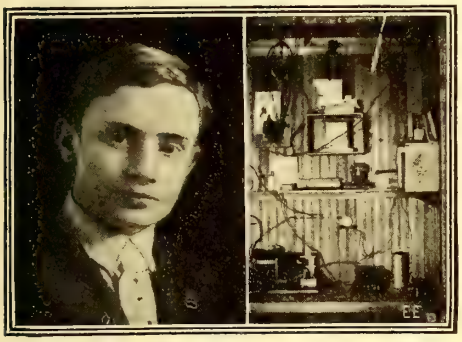
Rochester, N. Y.

PORTABLE WIRELESS SET OF J. F. RIEHLE.

The radio set here depicted is a compact, portable one, which can be placed on

Chief Signal Officer J. F. Riehle, and Compact Portable Radio Transmitting and Receiving Outfit Used by Co. A, Signal Corps, 2d Ohio Independent Regiment, Jr. O. U. A. M., Cincinnati, O.

the back of a Ford runabout. It consists of a ½-K. W. 110-volt transformer, a 1-inch spark coil, a rotary and stationary spark gap mounted on marble, 5 moulded condensers for sending, 2 detectors, 2 variable condensers, 1 for primary and 1 for secondary of loose coupler, a large loading coil, fixed condenser and 2 1,000-ohm 'phones, also a large oscillation transformer, aerial switch and 2 sending keys, 1 for alternating current and 1 for spark coil on battery. The set can be used on either 110-volt 60-cycle alternating current or 6-volt storage battery, only two connections having to be changed to shift from one to the other. The spark gap can also be converted from rotary to stationary by two changes in the posts of gap.



This outfit was used by Co. A, Signal

Corps of the 2d Ohio Independent Regiment Jr. O. U. A. M. (Incorporated) at Coney Island during a sham battle. The time required for setting up the collapsible poles, running the aerial and putting the entire set into operation was but 5 minutes. The poles are 50 feet high and the aerial is composed of No. 10 copper wires, each 85 feet long. I have been able to receive all of the coast stations, including Key West, but am not quite sure about the sending range, but I should think it would be somewhere around 100 miles. I am the chief signal officer of the Signal Corps, also an electrical inspector with the Cincinnati Fire Prevention Bureau, and therefore keep in touch with nearly all the amateur operators in my vicinity. J. F. RIEHLE.

Cincinnati, O.

ROBERT WITSCHEN'S WIRELESS OUTFIT.

Herewith I am submitting a photograph

Master Robert Witschen and His Neat Radio Station.

and description of my station. Not all of the apparatus that I own can be seen in this illustration. On the left you will observe my receiving outfit, which comprises a loose coupler, fixed condenser, 1,000 ohm single head-set and a Crystaloi detector. The sending outfit consists of a ½-inch coil, a home-made spark gap and a fixed condenser. The aerial has five wires on nine-foot spreaders and is 48 feet long and 48 feet high.

I should like to get acquainted with other amateurs within 60 miles of my station. My age is 15 years.

ROBERT WITSCHEN.

St. Cloud, Minn.

WEATHER FORECASTS BY WIRELESS.

A new scheme about to be inaugurated by the Weather Bureau will be the sending of weather reports to farmers by wireless. This experiment is to be tried out in Illinois and, if successful, the system will be spread to other States which request it. The messages will be transmitted at the rate of 10 or 12 words a minute to accommodate amateur operators who are not usually proficient enough to receive faster. An approved card has been provided whereon the receiving wireless operator copies the forecast message and posts it for the benefit of the public. Any farmer with an inexpensive receiving apparatus and a knowledge of the Morse code can obtain these forecasts by "listening in" while the station is sending them out.

RADIO STATION OF K. KERMET KRAMER.

The accompanying illustration is of my wireless station. The aerial is 32 feet high at one end and 40 feet at the other, and is composed of two copper wires 100 feet long. The receiving set consists of an Amco loose coupler, home-made loading

K. K. Kramer and His Effective Experimental Wireless Set. Sending Range 2 to 3 Miles. Hears N. A. A. and N. A .M. at Elizabeth City, N. C.

coil, Brandes' 2,000 ohm 'phones, Crystaloi detector, fixed and variable condensers and a buzzer test. The transmitting set is mounted in and on a mahogany finished box. It consists of a Mesco helix and key, spark gap, Leyden jar and auto spark coil. I can receive N. A. A., N. A. M. and many other stations very loud and clear. The sending set has a range of about two to three miles. K. KERMET KRAMER.

Elizabeth City, N. C.

Wireless equipment and a heliograph have been combined by a New York inventor in portable signaling apparatus for use on railroads or at sea.

Amateur News

Radio Club of America.

The December meeting of the Radio Club of America was held on Saturday evening, Dec. 4, in Fayerweather Hall, Columbia University.

L. J. Lesh, of the Aero Club of America, presented a paper on "The Development of Radio Sets for Aeroplanes." Mr. Lesh is the foremost worker in this field of radio work. The paper was plentifully illustrated by lantern slides of the recent tests conducted by Mr. Lesh and Emil J. Simon at the Curtis laboratories at Hammondsport, N. Y. Results of many interesting experiments with the "aerofan" were discussed.

The discussion following the paper was participated in by Fritz Lowenstein, E. J. Simon, L. G. Pacent, Paul F. Godley, Walter S. Lemmon and Ernest Amy.

The Cape May County Radio Association.

The Cape May County Radio Association, of Wildwood, N. J., which was organized in May, 1915, would like to hear from other clubs and amateurs within a radius of 100 miles.

The officers are: Edwin L. Chalmers, president; Edward N. E. Schlichting, secretary; Richard J. Anderson, treasurer.

All of the officers are licensed and have up-to-date sets.

Bradentown, Fla., Radio Club.

The amateurs of Bradentown, Fla., have organized under the name of the Bradentown Radio Club, with ten members at present. Meetings are held weekly in a small building which has been converted into a club room. The club has purchased a receiving set and intends to add sending apparatus as soon as possible. The club is anxious to get in touch with other amateurs or clubs in the State through its secretary, Hughson Hurlebaus, 439 Main street, Bradentown, Fla.

Amateur Radio Association of New Bedford, Mass.

The first meeting of the Amateur Radio Association of New Bedford, Mass., which was held at Mr. H. Johnson's station on Oct. 27, at 240 Chancery St., was a great success. The officers, elected for a term of three months, were as follows: President, Antone Sylvia; Financial Secretary, Horace Johnson; Station Inspector, Ralph E. Taylor. A committee was appointed to draw up a constitution for the association. The object of the association among amateurs is to develop a more extensive knowledge of wireless telegraphy. The members who attended the first meeting were Antone Sylvia, Horace Johnson, Henry Ackerman, Ralph E. Taylor, Frank Allen, William Pinnington, John W. Callaghan, Douglas Tripp, Stanley Wood and Anthony Hayden.

New Radio Club Organized at Rockaway Beach, N. Y.

Local amateurs have succeeded at last in organizing a radio club called the "Rockaway Radio Club" for the purpose of bringing together the many amateurs in this vicinity. Two successful and interesting meetings have been held in the club rooms at No. 296 Washington Ave., Rockaway Beach, L. I., the second of which resulted in a decided increase in membership. The following officers were elected: President, H. Conway; Vice-President, R. Richter; Treasurer, J. V. Byrue; Recording Secretary, Lewis Wagerer; Corresponding Secretary, H. Friegerlin; Sergeant-at-Arms, L. Anderson.

For the convenience of the members a library has been established and E. Richter and W. Byrue were appointed librarians to take charge of same. Address all communications to Rockaway Radio Club, 296 Washington Ave., Rockaway Beach, N. Y.

Election of Officers of the Arlington Radio Club.

At a recent meeting of the Arlington Radio Club of Arlington High School (Mass.), the following officers were elected: W. C. Clark, president; Eliott Perkins, vice-president; Harold O. Bixby, secretary and treasurer. The club has a large membership and will soon have both efficient transmitting and receiving sets in operation.

RADIO CLUBS ATTENTION!

We are always pleased to hear from young Edisons and Radio Clubs. Send a write-up of your Club with photos of members and apparatus to-day to: Editor "Amateur Gossip" Section, The Electrical Experimenter, 233 Fulton St., New York City.

New Radio Club in Akron, Ohio.

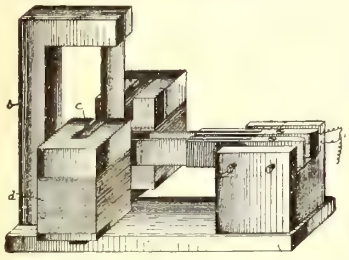
The Akron Radio Club, of Akron, Ohio, was recently organized and the following officers were elected: Jack Gritton, president; Donald Hoffman, vice-president; Clarence W. Brown, secretary; Virgil Baysinger, treasurer; Darley Thurmes, exchange manager; Roland Palmer, electrician, and Howard Myers, inspector. The club has twenty-two members at present. Meetings are held weekly at the president's home. The club members would like to communicate with other radio clubs. Address all communications to Clarence W. Brown, R. F. D. No. 25, Akron, Ohio.

Association at Pensacola, Fla.

There was organized in Pensacola, Fla., on the first of January, 1916, a radio association which will be for the benefit of the amateurs of United States and Canada. It will be operated on a new basis which will be more of a help to the amateur and laymen than any other association in the country.

All amateurs interested in this movement please write for full information to T. H. Moore, Jr., 321 North Spring street, Pensacola, Fla.

The Carrollton Radio Inter-Communication Club.



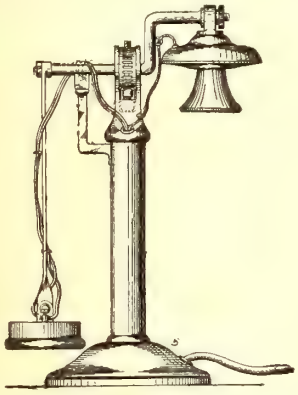
The Carrollton Wireless Club was reorganized in the laboratory of the public school at Carrollton, Ill., Nov. 24, as the Carrollton Radio Intercommunication Club. The following officers were elected: Ward Dickson, president; David Roberts, vice-president; Stuart W. Pierson, secretary and chief operator; Owen Jarboe, treasurer. The purpose of the organization is to regulate the radio work in Carrollton, to make the members proficient operators and to study the art of radio communication. The club will meet every other Tuesday. At each meeting papers pertaining to some special topic are read and then discussed. The secretary would like to hear from any one wishing to get in communication with Carrollton, Ill.

LATEST PATENTS

Resonating Relay.

(No. 1,166,951; issued to Hans von Kramer and Gilbert Kapp.)

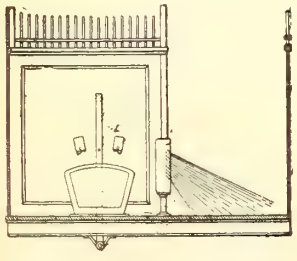
This device involves valuable factors controlling the movement of contacting or circuit-closing vanes.



These factors may be varied in different ways and a relay can be tuned to respond to any desired frequency within certain limits. This device is capable of being operated by very feeble alternating currents and when so acuated can close the circuit in the usual manner. The magnetic circuit is permanently magnetized.

Telephone Attachment.

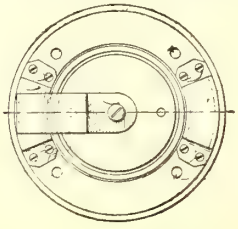
(No. 1,163,326; issued to David Y. Donaldson.)



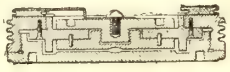
An improved form of telephone desk set whereby the transmitter and receiver are mounted on a revolving arm. Normally the transmitter and receiver hang downward so as to be dust and germ proof. The receiver is also mounted on a rigid arm, so as to be held in the proper position when the apparatus is revolved for talking, thus doing away with the task of holding the receiver to the ear.

An Elevator Door Light.

(No. 1,164,301; issued to Charles E. Moore, asignor to Elevator Supply & Repair Co.)



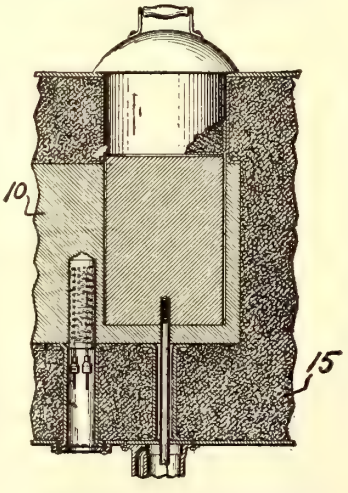
A threshold illuminator for elevators, etc., whereby the floor at the opening of the doorway is lighted to prevent persons from tripping. Whenever the car stops, the lamps, which are arranged in a special reflector as observed, are switched on automatically and off again as the car proceeds on its journey. This arrangement is now in use in some of the largest office buildings where it has proved invaluable in the prevention of accidents.



Quenched Spark Gap.

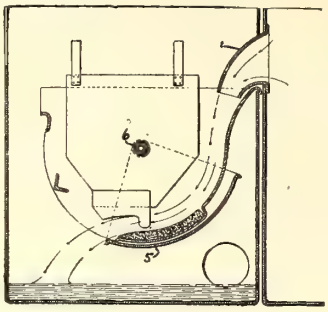
(No. 1,163,568; issued to Frederick G. Simpson.)

This patent relates to the design of quenched spark gap units intended to be interchangeable and comprises a special insulation ring into which are threaded the metal sparking surfaces of substantial size. The gap is thus particularly rugged. Again the various parts are made of materials having nearly the same coefficient of expansion, so that no variation of the spark gap length can occur due to heating of same.



Electric Heat-Storage System.

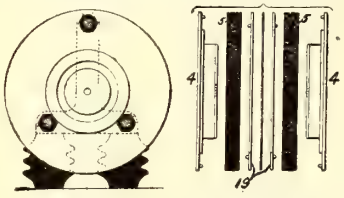
(No. 1,161,748; issued to William Stanley, assignor to General Electric Company.)



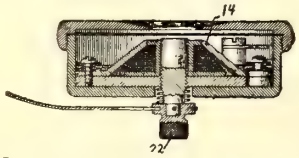
This invention relates to an improved method of storing heat electrically and pertains especially to the arrangement and selection of the heat absorbing materials. A metal container 10, is placed in a quantity of heat storing material 15 (electric furnace sublimation products containing silicon, for instance). Means are provided in the design suggested, whereby the heat developed is automatically regulated according to the temperature of the heat storage materials, as by using iron wire in the electric resistor.

A Liquid Rheostat.

(No. 1,161,746; issued to George Squire, assignor to General Electric Co.)



The inventor of this rheostat of the liquid type, endeavors to improve the efficiency of the same, especially as to the proper cooling of the fixed electrodes. A liquid is introduced through an upper nozzle 1, the discharging orifice of which may be changed as desired by swinging the segmental apron 5, upward on its axis 6. In this manner the liquid carrying current is constantly flowing past the fixed electrodes and has but little chance to heat, besides cooling the tips of these electrodes in a very efficient manner.

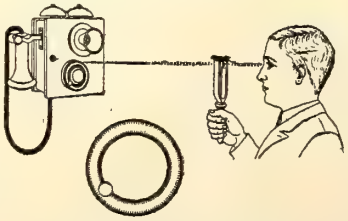


Quenched Spark Cap.

(No. 1,161,520; issued to Richard Pfund.)

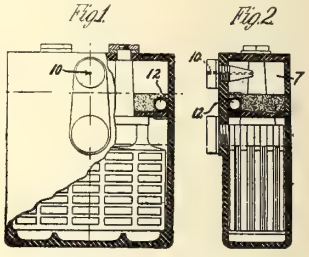
A quenched spark gap improvement intended to do away with the thin and delicate insulating washers now in vogue. In this design a heavy insulating washer 5 is used, also two metal plates 19, and between these are placed a metal spacing washer 7. Cooling vanes of metal are placed between every gap or against plates 4 and 4, for instance. It will be seen that this design offers many advantages over that ordinarily in use nowadays.

Telephone Receiver.



(No. 1,166,152; issued to Thomas Rhodus, assignor to The Magniphone Co.)

This is an improvement on the electromagnetic type of telephone receiver, designed so that the magnet coil will occupy the minimum amount of space and thus provide as large a (sound) resonance chamber within the receiver as possible. The yoke of the electro-magnet is in the shape of an iron cone 14. The center core may have its air gap before the diaphragm varied by means of an adjusting nut 22. The spiral spring under the nut takes up any lost motion in the core thread.

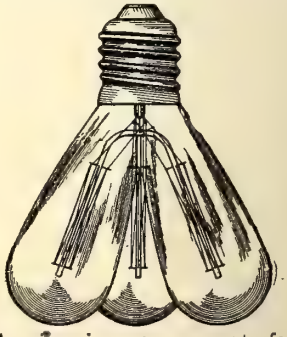


Telephone Synchronizing Device.

(No. 1,160,356; issued to Arthur H. Adams, assignor to Western Electric Company.)

This device is intended for the purpose of simplifying the synchronization of automatic telephone calling discs The disc itself, or a paper template fitting over same, is provided with two circles composed of black points. When these are viewed through the tuning fork synchronoscope as perceived, they appear to be stationary if the speed of the disc is correct.

It will be obvious that for the tuning fork shown and described herein there may be substituted any other device by which a slit opening could be presented before the observer with a frequency as in the case assumed, for example, of 110 per second. It will also be obvious that the invention may be adapted to any desired maximum or minimum speeds of rotation, and that the number of projections stamped or printed upon the card or disc may be changed either with or without a corresponding change in the periodicity of the tuning fork or equivalent device.



Storage Battery Vent.

(No. 1,160,491; issued to Phelps Brown.)

Ingenious device for venting storage batteries of the acid type. A splash chamber 7, is provided with a peculiarly shaped tube 12, joining this chamber with the one below containing the plates of the cell. In this fashion gas may pass up into the splash chamber and out through the perforated plug 10. Any acid splashing into the upper chamber will readily pass back through the tube 12, and it is claimed that when properly designed that no capillary leakage of the electrolyte can take place.

Electric Cluster Light.

(No. 1,169,346; issued to Thomas O'Donnell.)

An ingenious arrangement for combining several electric lamp bulbs into a common unit, as perceived from illustration. A very good idea for lamps which are to be used in public places, etc., and capable of giving a more even distribution of the intrinsic brilliancy than when one bulb is used with a concentrated filament of equivalent candlepower. A standard Edison screw base may be used for this cluster lamp. The filaments may be connected on multiple or in series as the manufacturer may elect.

COPIES OF ANY OF THE ABOVE PATENTS SUPPLIED AT 10c. EACH.

Phoney Patents

Under this heading are published electrical or mechanical ideas which our clever inventors, for reasons best known to themselves, have as yet not patented. We furthermore call attention to our celebrated Phoney Patent Offizz for the relief of all suffering daffy inventors in this country as well as for the entire universe.

We are revolutionizing the Patent business and OFFER YOU THREE DOLLARS ($3.00) FOR THE BEST PATENT. If you take your Phoney Patent to Washington, they charge you $20.00 for the initial fee and then you haven't a smell of the Patent yet. After they have allowed the Patent, you must pay another $20.00 as a final fee. That's $40.00 ! ! WE PAY YOU $3.00 and grant you a Phoney Patent in the bargain, so you save $43.00 ! ! When sending in your Phoney Patent application, be sure that it is as daffy as a lovesick bat. The daffier, the better. Simple sketches and a short description will help our staff of Phoney Patent examiners to issue a Phoney Patent on your invention in a jiffy.

PHONEY PATENT OFFIZZ

No. 1492 / 23° S.W.

Patent Applicated September Morn, 1813

AN ELECTRO-MECHANICAL BREATHMOTOR

To whom it may confound:

Be it known that I, O. Bedamed, a denizen of Luny Park and a resident of the local Institution, second floor, padded cell number 4, have invented a new and useful Improved Means for generating current, of which the following is a full, intoxicated execution.

This invention relates to a means for utilizing the heretofore wasted energy generated by mankind, and has for an object the production of electric power.

Another object is the utilization of waste muscular energy. (The word waste has no reference to Her waiste.)

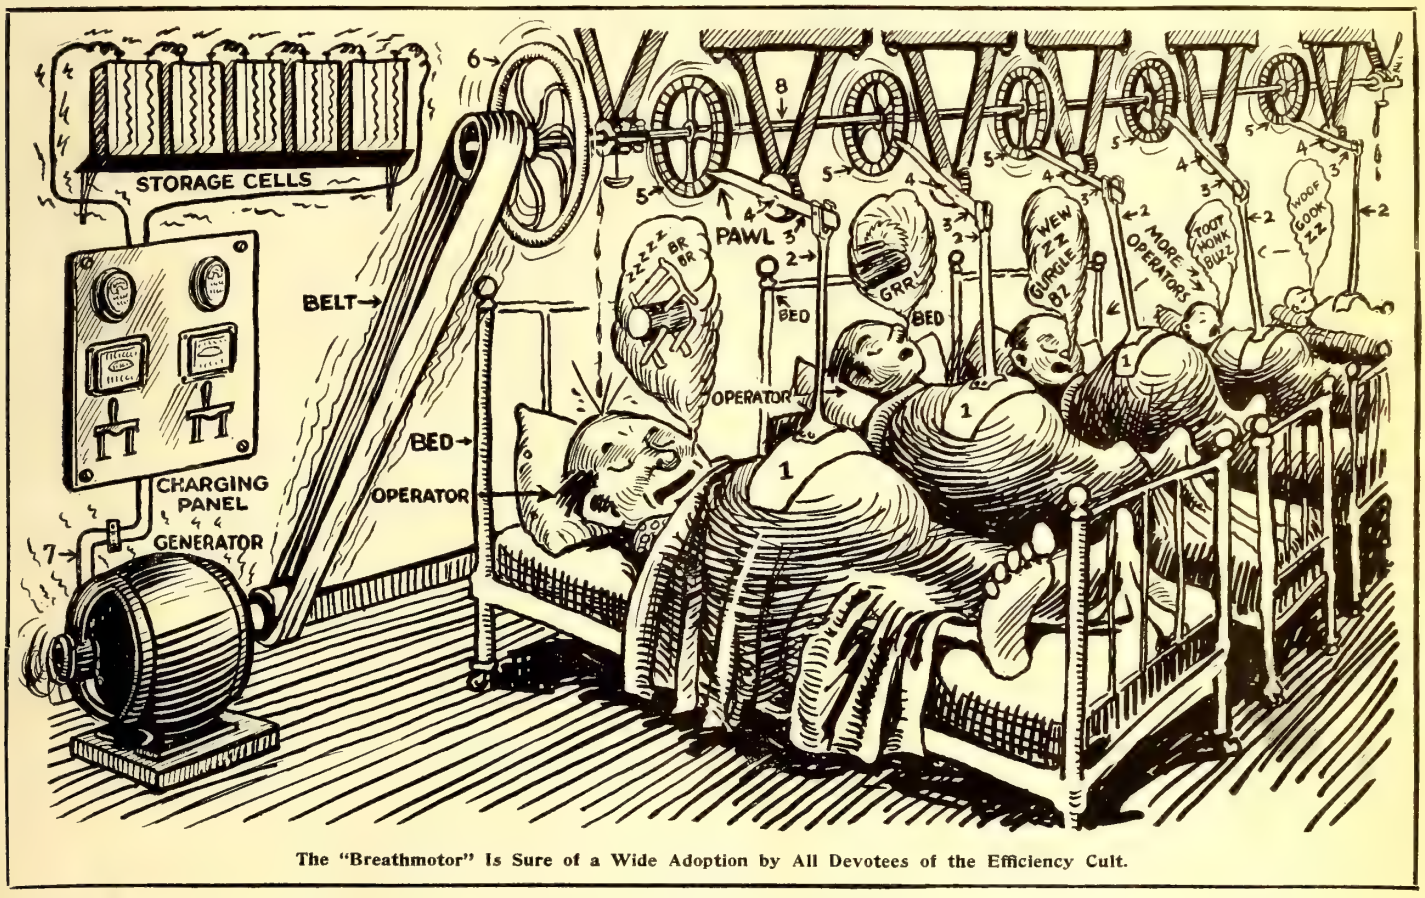
This invention converts the perpendicular movement of chest and stomach by means of levers, ratchet wheel, belt, and dynamo, into electrical energy, which said energy may be disposed of in various ways, such as heating a Chicken incubator, or operating an automatic spanker for conserving the skin on the palm of Father's hand.

The action of the apparatus is as follows: The victim retires (this does not have reference to a Ford owner) and assumes a horizontal position with the stomach uppermost. The petitioner assumes that the operator is a man, for said petitioner has no knowledge of the anatomy of the gentler sex, and cannot affirm his belief to the presence of said stomach in said sex. Said petitioner has been informed, however, that the gentle cow has six stomachs.

When said position is assumed the stomach is in position to do overtime work, and for every inhalation and exhalation there will be a movement of attachment 1 (which is erected to conform with the natural formation of the protruberance) and a corresponding movement of the rod 2 and the lever 3, which moves on axis 4; the end of the lever 3 has attached thereon a pawl which engages with the ratchet wheels and produces a circulatory movement to the balance wheel, 6, and to the shaft on which said wheel is attached. This motion is transmigrated to the dynamo, 7. If the speed is too slow, a governor, 8, connects a current to the victim, and causes his respiratory action to increase surprisingly.

What I claim is:—

1. A breathmotor which will utilize the energy wasted by bums, loafers, and tinhorn sports who wear checkered clothes and put their thumbs in their suspenders. This arrangement will be a boon to women who have said bums, as they can run a washing machine, butter churn, wood saw or ensilage cutter by electricity.



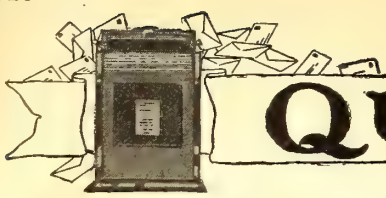
4. A breathmotor by which energy can be collected in such places as Hotel De Gink, Hoboes' Heavenly Home, Weary Willie's Wresting Palace, and Trusting Tramps' Tryst.

19. A breathmotor which will earn 1,765 per cent. on investments in free lodging houses by generating, without cost, sufficient current to light Broadway, Chinatown and Sing Sing.

In testimony whereof, I firmly fix four former friends' fingerprints in the presents of these two tired and totally trustworthy allies, and witnessed this 30th morning of Februember, 1812.

(Signed) O. BEDAMED,
By his attorney,
F. S. Schlink.

Witnesses: I. M. Busted, Gosh A. Mity, Hoop S. Mydeer.



The "Breathmotor" Is Sure of a Wide Adoption by All Devotees of the Efficiency Cult.

BUZZER AWOKE HIM TO SPY ON SPOUSE.

Electrical dealers in Washington, D. C., are making the most of the published announcements of a recent divorce suit in that city. The case is that of Mrs. Emma S. Bullis against Dr. M. C. Bullis.

In his cross-bill the doctor told how he kept track of his wife's movements during the night, although she slept in an adjoining room. He attached two small wires to the door of her room, connecting them through an electric battery to a small buzzer on a cord, which he wore around his neck. The moment his wife's door opened or closed he was awakened and was on the *qui vive.*

QUESTION BOX

This department is for the sole benefit of the electrical experimenter. Questions will be answered here for the benefit of all, but only matter of sufficient interest will be published. Rules under which questions will be answered:

1. Only three questions can be submitted to be answered.
2. Only one side of sheet to be written on; matter must be typewritten or else written in ink, no penciled matter considered.
3. Sketches, diagrams, etc., must be on separate sheets. Questions addressed to this department cannot be answered by mail.

COMPOUND WOUND DYNAMO.

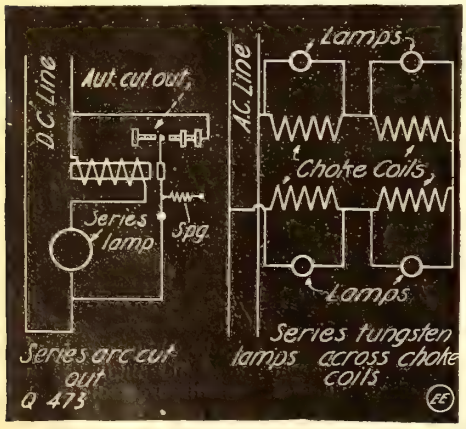
(471.) L. A. Madison, Kingman, Me., wishes to know: 1. What is the largest motor he can run on the current from a 125-volt, 44-ampere dynamo. 2. Whether it is possible to operate a compound wound dynamo in the reverse direction and obtain current from same. 3. The receiving range he would have using an aerial 100 feet long and 75 feet high, with a galena detector, tuning coil, variable condenser and 2,000 ohm 'phones.

A. 1. The largest motor that you can run with this dynamo is about 7 h.p.

A. 2. A compound wound dynamo can be run in the reverse direction providing the windings of the series field and armature are changed, or the shunt field winding may be reversed.

A. 3. The distance which you can receive with the apparatus mentioned would be between 900 and 1,200 miles. This distance would be increased under favorable atmospheric conditions.

HIGH FREQUENCY COIL.



(472.) John A. McGuire, Ridgewood, N. J., asks: 1. Whether the high frequency outfit described in the November, 1915, issue of *The Electrical Experimenter* can be operated on spark coils. 2. Whether a 2-inch coil would operate this outfit.

A. 1. The high frequency outfit you mention will work on a 6-inch spark coil.

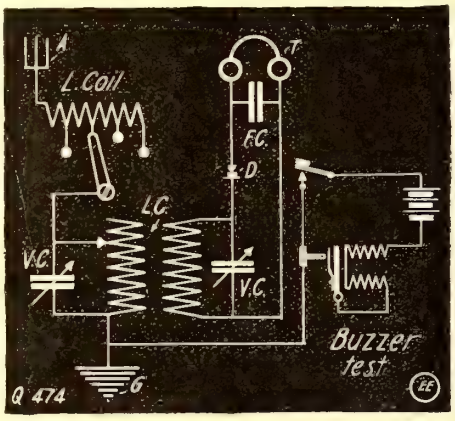
A. 2. It will not work efficiently on as small a coil as a 2-inch one.

STREET ARC LIGHTS.

(473.) Claude Martin, Brownwood, Tex., desires to know: 1. How street arc lights are connected in series so that when one burns out it does not affect the other lamps; also how this works out in series tungsten lighting schemes. 2. Why he was not able to charge a one pint Leyden jar

Automatic Cut-outs Used in Series Lighting Systems.

with a ½-inch spark coil. 3. Whether the Standard Electrical Dictionary by Prof. O'Connor Slone is self-pronouncing.



A. 1. This system is so arranged that a cut-out properly connected to each lamp, automatically operates a switch which will keep the other lamps still burning when one lamp burns out. The diagram herewith shows how this cut-out is connected.

A. 2. The reasons for not being able to charge the Leyden jar with a ½-inch coil is perhaps due to the fact that the jar was punctured, thus allowing the spark to pass through the dielectric.

A. 3. The dictionary is not a self-pronouncing one. We believe that it is impossible to obtain such a dictionary.

SLATE SWITCHBOARD.

(474.) Albert R. Saunders, New York City, wishes us to give: 1. The connec-

Radio Receiving Hook-up with Buzzer Test.

tions for loose coupler, duplex loading coils (four of different capacities), two variable condensers, fixed condenser, galena detector with buzzer test and 'phones. 2. What size wire and how much in each loading coil of the following dimensions: 1,000 meters, 1,400 meters, 2,000 meters, 2,500 meters. 3. How slate can be cut and drilled for a switchboard.

A. 1. The accompanying illustration gives the connections you desire.

A. 2. The following is the size and quantity of wire required for the various loading coils: For 1,000 meters, 330 feet; 1,400 meters, 450 feet; 2,000 meters, 660 feet; 2,500 meters, 850 feet, all No. 24 S. C. C. magnet wire.

A. 3. Slate is usually cut with a hack saw and drilled with twist drills, applying water to the drill in order to soften the slate.

THE FOURTH DIMENSION.

(475.) Morris K. Jessup, Rockville, Ind., desires us to tell him: 1. How to make a selenium cell. 2. Where he can find a book on the "fourth dimension."

A. 1. Selenium cells are usually made by winding two separate wires on an insulating material, such as mica, and applying a very thin coat of metallic selenium over same. After the metallic selenium has been applied the cell is carefully annealed. This process of annealing is accomplished by placing the cell for two to three hours in an oven and keeping the temperature just a few degrees below the melting point of the selenium. It is then allowed to cool gradually.

Our August, 1914, issue contained an excellent method of making selenium cells.

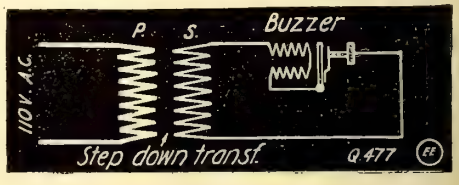
A. 2. The best book on this subject, "A Primer of Higher Space" (the fourth dimension), is supplied by us at $1.25 prepaid.

VARIOMETER.

(476.) Lloyd Bossirman, Pleasanton, Kan., wishes us to tell him: 1. The size and amount of wire necessary for building a variometer. 2. The wave length obtained by the use of above mentioned variometer and a loss coupler, the primary of which is 9x5¼ inches, with an antenna of two wires 500 feet long and a 50-foot lead-in. 3. The time that Fort Riley and Fort Leavenworth, Kan., and St. Louis, Mo., operate.

A. 1. The size of wire necessary for building the variometer would be No. 18 S. C. C. magnet wire, and the amount would depend upon the size of the coil. We think that about 50 feet of this wire would be required for winding the two coils.

A. 2. The wave length obtained with the above-mentioned instruments and the specified antenna would be about 5,000 meters.



3. These stations do not have any particular time for operating.

WAVE LENGTH.

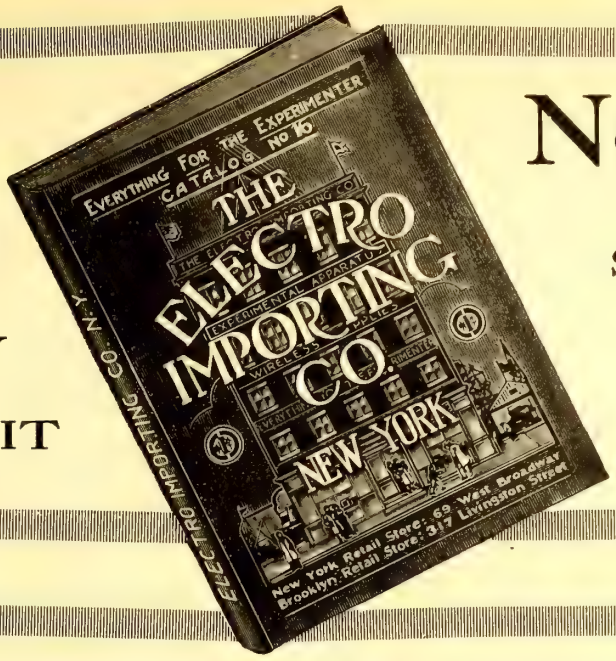
(477.) Bernard J. Bisciotti, Philadelphia, Pa., desires to know: 1. The wave length of his antenna, which is 44 feet long and 40 feet high, composed of four wires with a lead-in 10 feet long and a 6-foot ground connection. 2. Whether it is necessary for him to notify the Radio League of America when he installs a transmitting set? 3. How to hook up a buzzer to be operated on a 110 volt, alternating current line?

A. 1. The approximate wave length of your antenna is 150 meters.

A. 2. It will be necessary for you to no-

Operating Buzzer on Low Voltage A. C.

tify the Radio League of America whenever you install your transmitting set.



A. 3. The illustration herewith shows the connections for the buzzer which is to be operated on a 110-volt, alternating current line, utilizing a step-down transformer.

KICK-BACK PREVENTER.

(478.) Herbert T. Hintgen, Wahpeton, N. Dak., asks: 1. About some trouble with his electrolytic interrupter. 2. The approximate resistance of the carbons of dry cells.

(*Continued on page* 722.)

AUDIO-ROTOR

CQ! CQ! CQ!

Important news messages from high powered stations using the undamped wave are passing over your aerial. The AUDIO-ROTOR connected in any receiving system enables you to copy the undamped wave without the use of other devices.

MONOTONE QUENCHED SPARK GAP

For Undamped Wave Receiving

Copy Tuckerton, Sayville, Arlington, Nauen, Honolulu, Darien. This little instrument will do wonders you never dreamed of. *Price $5.00, prepaid.*

Quiet in Operation, Arcless, Penetrating

Already used by hundreds of operators. Only one unit required for spark coils. Transformers require two units for every ¼ KW Power. *Per unit $1.50, prepaid.*

RICHARDSON COMPANY, Commerce Bldg., ERIE, PA.

QUESTION BOX.

(*Continued from page 720.*)

3. Whether the kick-back preventer described in the February, 1916, issue of this magazine would be sufficient for the operation of a 1-kilowatt radio transformer?

A. 1. The chemicals in the construction of your electrolytic interrupter are not the right kind, and therefore you have not obtained the satisfactory results. You should use a dilute solution of sulphuric acid composed of one part of the acid to five parts of water.

A. 2. The approximate resistance of the carbons of dry cells is 1/10 to 1/5 ohm.

A. 3. The kick-back preventer described in the February issue can be used with a 1-kilowatt transformer, but we would advise you to obtain a larger one for best results.

10,000 METER LOOSE COUPLER.

(479.) Joseph Frick, Chicago, Ill., wishes us to give him: 1. Details for constructing a 10,000-meter wave length loose coupler and size and kind of wire used. 2. Information regarding the possibility of receiving Lake Bluff, with the use of a tikker in the circuit.

A. 1. A loose coupler having a wave length range of 10,000 meters can be built as follows: The primary of coupler should be 18 inches long and 6 inches in diameter, while the secondary should have a length of 17 inches and diameter of 5 inches. The primary should be wound full of No. 22 copper enamel magnet wire and the secondary with No. 24 copper enamel magnet wire. The taps should be taken out on the primary at every 30 turns and likewise with the secondary.

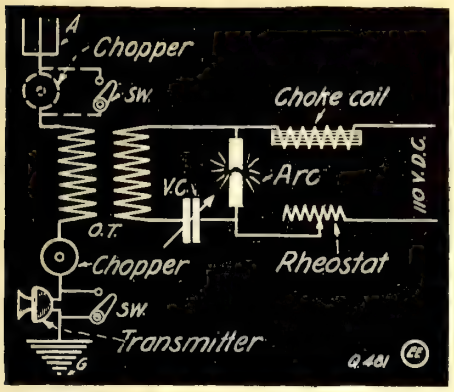
A. 2. With the aforedescribed loose coupler you should have no trouble in receiving Lake Bluff station with a tikker connected in circuit.

ARC EFFECTS.

(480.) Kenneth Preston, Ashland, O., inquires: 1. How he can eliminate the noises developed by an electric arc, which is located near his station? 2. The dimensions of a loading coil necessary for receiving *Sayville,* L. I.?

A. 1. We would advise you to construct a small auxiliary antenna parallel to the arc light transmission line, connecting the aerial to the ground. (This aerial is, of course, not used for wireless purposes.) Another method which you can use to eliminate the noises developed by the arc is to change the direction of your antenna. However, the former method would be preferable.

A. 2. A loading coil which will tune Sayville, L. I., station can be constructed by employing a tube which is 20 inches long by 5½ inches in diameter, fully wound with one layer of No. 22 B. & S. copper enamel magnet wire.



"CHOPPER" FOR ARC CIRCUITS.

(481.) Lloyd Bosserman, Pleasanton, Kan., sends us a diagram of a radio telephone set, on which he would like to have our opinion as to whether it is correct. 2. He also requests a diagram showing the connection of a "chopper" in the electric arc circuit.

A. 1. The diagram submitted is correct and you will no doubt find it satisfactory for operating over short distances.

A. 2. The accompanying illustration shows the connection for the "chopper." It can be connected in series either with the ground or with the antenna lead. When the station is to be used for the transmission of radio telephonic messages it is only necessary to short circuit the terminals of this instrument. You will undoubtedly find the "chopper" satisfactory for transmitting

radio telegraphic signals or for calling when using the arc for the production of high frequency oscillations.

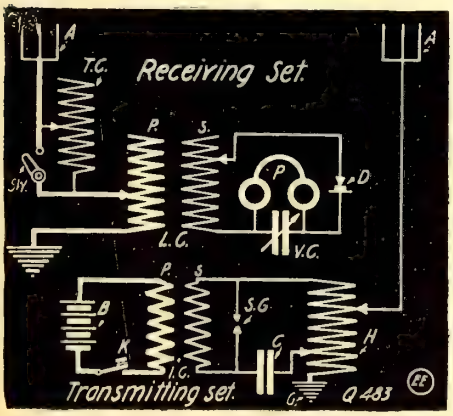
Connection of "Chopper" in Radiophone Circuit.

RECEIVING RANGE.

(482.) Chester Barnes, Linton, Ind., wishes us to tell him: 1. How far he would be able to receive with the following instruments: Receiving transformer, rotary variable condenser, fixed condenser, 2,000-meter loading coil, Murdock detector, 3,000-ohm receivers. 2. Whether a loading coil increases the value of the receiving range. 3. The best detector for use in wireless telegraphy.

A. 1. With these instruments you should be able to receive 800 to 1,200 miles under favorable conditions. This can, of course, be increased by using a large antenna.

A. 2. A loading coil is only used for receiving longer waves than the natural wave length of your antenna. It is not necessary to tune for such unless the distant station is transmitting a longer wave length than your normal receiving set responds to.



A. 3. The two best detectors used in wireless receiving stations are possibly the Audion and Radioson detectors.

RADIO HOOK-UPS.

(483.) Vincent Natalish, New York City, wishes to have: 1. A hook-up for the following instruments: A Navy type loose coupler, variable condenser, detector, 'phones and switch for cutting in a loading coil for increasing the wave length. 2. Diagram for a one-inch spark coil gap, helix, condenser or Leyden jars and key. 3. Information regarding which is preferable—Leyden jars or unit condensers of other types.

A. 1. The accompanying diagram gives the connections for the instruments you mention.

A. 2. The second illustration shows the

Radio Sending and Receiving Circuits.

connections for the transmitting instruments you have specified.

A. 3. It is more advisable to use sec-

"I Received Messages from San Francisco (2100 Miles) with CRYSTALOI"

"July 9th, while at anchor in Kahului Harbor, Hawaiian Islands, I copied K P H San Francisco Press with Crystaloi, at a distance of 2100 miles."

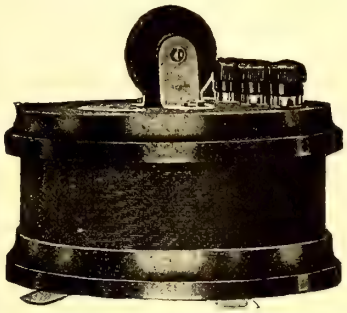
CRYSTALOI

The Highly Sensitive, Permanent

WIRELESS DETECTOR

Is Making New Records Like This Every Day

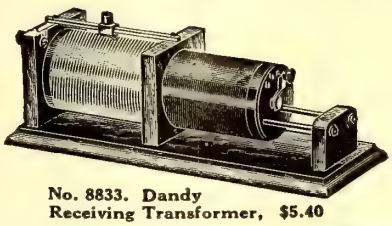


Crystaloi is the only practical wireless detector affording innumerable contact points. Due to its peculiar construction, embracing a very sensitive mineral which is brought into contact with a light, finely divided alloy, it is remarkably free from static and other interferences. Tests have shown that Crystaloi actually reduces static one-half. With proper use it will last a lifetime without repair, adjustment or attention of any kind.

3 TYPES
Crystaloi.

TYPE O—Dimensions 2¼" x 1⅞". **Price, $3.50.** Mailing Weight, 1 lb.

TYPE AA—Equipped with a cohering inductance—Dimensions 4" x 3½". **Price, $6.00.** Mailing Weight, 2 lbs.



TYPE BB—Equipped with cohering inductance, fixed condenser, buzzer, test and frequency control. Dimensions, 7½"x 5½" x 3½". **Price, $12.00.** Mailing Weight, 4 lbs.

TYPE AA. SUPER-SENSITIVE

All Live Dealers Carry Crystaloi. If your dealer cannot supply you, write us. Catalog "C," fully describing Crystaloi and all of our other High-Class Receiving Apparatus, sent on receipt of 5 cents in stamps.

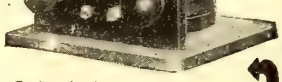
NEW WIRELESS WONDER

THE INSTANT RADIOGRAPH

Greatest invention of the Age. The result of years of experimentation.

Abolishes detector troubles and adjustments—
No more delays—no more lost time and messages

Pick up your receivers any time, Summer or Winter, in any atmospheric conditions and—



You Can Receive Instantly Without Any Adjusting

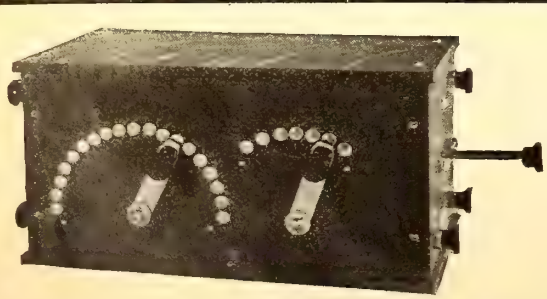
3,000 miles is latest record of the Instant Radiograph.

It is wonderful, but true, you cannot get the Instant Radiograph out of adjustment no matter how you knock it about. Try it yourself, hit it with a hammer while in use.

Vibrations, jars, knocks cannot affect it as there are no fine adjustments to make—no batteries—nothing to wear out—no operating expense whatever.

INTRODUCTORY PRICE FOR MARCH **$3.00**

Cut ¼ Actual Size.



The Instant Radiograph is more efficient than any detector on the market, as there is nothing to adjust.

The Instant Radiograph is beautifully and solidly constructed on a heavy base of hard rubber 4 x 4 inches square with rounded corners and 4¼ inches high; binding posts are made of non-corroding metal, heavily silver plated, and have heavy rubber-covered thumb screws, preventing current leakage. **All contacts are large, non-corroding, heavily silver plated, of large size and will last a lifetime. This is a wonderful instrument of distinctive appearance that you will be proud to have in your wireless station.**

The Radiograph is the greatest recent invention in the Wireless field. Its value is priceless and as we want every professional and amateur operator on land and on board ships to use it, we have decided to make an introductory price of $3.00 for a limited time only. This is only one-third of the price at which it should be sold. Send your order at once. **Send for free Catalog E of the Instant Radiograph.**

You need this new book. "Radio Stations of the World." A complete authentic list of call signals of every public wireless station. Price, only 50c.

UNIVERSAL WIRELESS COMPANY, 19 East 32nd St., New York

This Selective and Efficient Tuner Only $8.00

"Your new tuner with switches is very satisfactory and much more selective and efficient than other type although that one does splendid work. Henry Wheat, Jr., Geneva, N. Y."

We also make a 10,000 meter tuner. Send 2-cent Stamp for Bulletin 107

Colby's Telegraph School
Auburn, N. Y.

tional condensers in a transmitting station than Leyden jars, as the former are less bulky.

TELEGRAPHONE QUERIES.

(484.) Joseph A. Wensk, Baltimore, Md., wishes to know: 1. Whether the plates and supports of the Telegraphone, which was described in the June, 1915, issue of *The Electrical Experimenter,* can be built of wood instead of aluminum? 2. Whether he can receive the Sayville station with the use of Dr. Cohen's new receiving set hook-up? 3. The quantity and size of wire required to build two coils, each have 15 ohms resistance.

A. 1. These parts could be satisfactorily built of wood, but the wear and tear on same is such that if they are built of aluminum they will last much longer.

A. 2. You will undoubtedly be able to receive the Sayville wireless station by the use of Dr. Cohen's improved hook-up if a proper inductance is added to your antenna circuit. We would advise you to obtain a very large inductance, having at least a wave length of 7,000 meters, as the wave length used by this station is about 9,000 meters.

A. 3. For building these coils we would suggest to use 640 feet of No. 36 B. & S. copper magnet wire.

DRY BATTERIES.

(485.) William Entress, Unionport, N. Y., wants to know: 1. The compound used in making dry cells and the quantity of same. 2. Whether a Geissler tube can be operated on a small medical coil?

A. 1. The moisture retaining compound used in constructing primary dry cells is: Ammonium chloride, 1 part; plaster of paris, 3 parts; zinc oxide, 1 part, and a sufficient amount of sawdust to cover the paste.

A. 2. A small medical induction coil will not operate a Geissler tube. You must use a coil giving at least a one-eighth inch spark.

LOOSE COUPLER.

(486.) Edward Updike, Niles, Mich., wishes us to tell him: 1. Whether a loose coupler would be improved if the primary of the coil were wound over an iron tube? 2. Whether a resistance should be connected in series with an arc.

A. 1. The primary coil of a loose coupler should never be wound over an iron core, as the impedance of the coil would be increased and thus inferior results would be obtained. However, other metallic tubes can be employed experimentally if desired, but careful insulation must be made between the tube and the winding. Also the tube should be slit longitudinally, to prevent eddy currents circulating through it. The iron core cannot magnetize and demagnetize fast enough for this purpose, resulting in a very low "power factor" and consequent loss.

A. 2. A resistance should invariably be used with the arc.

CHANGING A. C. TO D. C.

(487.) John T. Alderman, Jr., Henderson, N. C., wants to know: 1. Whether a ½-kilowatt radio transformer can be used for operating an X-ray or Tesla transformer? 2. Whether a buzzer transmitter can be made from an ordinary buzzer? 3. How 110 volt, A. C. can be converted into D. C.?

A. 1. A ½-kilowatt transformer can readily operate an X-ray or Tesla transformer, providing it is not too large.

A. 2. A buzzer transmitter can be made from an ordinary buzzer. However, larger coils should preferably be used in building such a device, so that a greater amount

VIOLET RAYS

NEWEST FORM OF ELECTRICITY FOR YOUR OWN PERSONAL USE

The VIOLETTA HIGH-FREQUENCY GENERATOR is used and endorsed by thousands of physicians. It generates the Violet-Ray High-Frequency Current which is used with wonderfully quick results for facial, scalp, and body treatments.

Compact, efficient, operates on alternating or direct current, and **absolutely safe** and guaranteed. A scientific marvel in construction.

Write for our beautifully illustrated booklet 62 G.

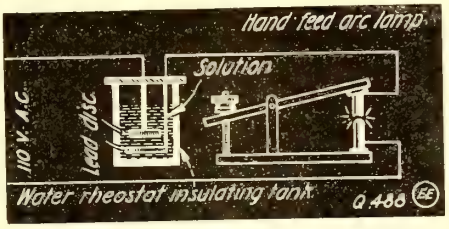
READ the Classified Advertisements in this issue. They are small but contain big bargains and opportunities.

of current can be supplied to the coils and thus a greater range obtained.

A. 3. There are two methods by which you can readily convert 110 A. C. to D. C. One is to employ a rotary converter of the electrical type or a mechanical converter. The second and easier method, although not as efficient for converting same, makes use of an electrolytic rectifier.



WATER RHEOSTAT.

(488.) Clarence F. Kramer, Lebanon, Ind., wants to know: 1. How many small incandescent electric bulbs can be lighted by the current generated from an ordinary three-bar telephone magneto? 2. How it is possible to step-down 110 volt, 60 cycle A. C. to such a voltage as would operate a hand feed arc lamp? 3. Whether it is possible to employ a water rheostat for reducing said voltage to the proper value for operating the arc lamp?

A. 1. Only by rewinding the magneto with, say, No. 24 enamel wire will you be able to light up about two six-volt, two-candlepower lamps. The ordinary magneto uses very fine wire, usually No. 36 or finer, with a resistance varying from 600 to 10,000 ohms. Such a magneto will not light a lamp.

A. 2. The 110-volt, 60 cycle A. C. can be reduced to a suitable value for operating a hand feed arc lamp by employing a water rheostat.

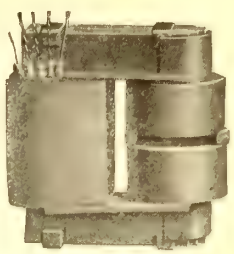
A. 3. You can readily use a water rheostat for reducing 110 volts. The accompanying illustration gives the method for connecting the rheostat.

Use of Water Rheostat in Arc Circuit.

USES FOR OLD PHONOGRAPH RECORDS.

(489.) H. M Clay, Shelbyville, Ky., wishes to know how he can melt old phonograph records so that he may use the molten material for making parts for wireless instruments?

A. The best method by which you can melt the phonograph records is to employ an ordinary carpenter's glue pot, filling the inner chamber with broken parts of the record and the external chamber with water and then applying a low heat to the pot. Care should be taken to see that the molten material does not burn, as it can readily catch fire and thus destroy its insulating properties. You will obtain better results with a good grade of stationer's sealing wax.



SPARKING UNDER DYNAMO BRUSHES.

(490.) H. A. Wright, West Barnstable, Mass., wishes us to tell him: 1. The size of wire to be used in building the armature and fields for a two pole, shunt wound dynamo developing 12 volts. 2. The cause of sparking at the commutator.

A. 1. We would advise you to use No. 28 wire on the field coils and No. 26 copper magnet wire on the armature coils.

A. 2. The cause of sparking under the brushes may be due to several reasons, some of which are as follows: The brushes possibly may not be set correctly, pressing too hard or unevenly against the commuta-

UNMOUNTED TRANSFORMER

You Can Get Results

with a small condenser and this transformer

It is a 1-2 K. W. size and is built on the same specifications as to material and workmanship, etc., as our big central station transformers.

Hundreds of stations are now using these transformers. This transformer gives you 13,200 volts.

Let us tell you how you can do part of he work yourself and get this transformer at a remarkably low cost.

THE PACKARD ELECTRIC CO.
555 Dana Avenue Warren, Ohio

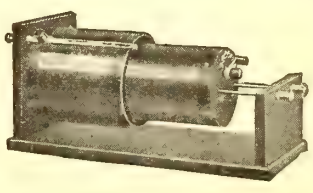
Type AML

The Precision Varicoupler

Patented Mar. 7, 1916, foreign patents pending.

Up-to-date receiving circuits require improved apparatus. You can't get supersensitiveness with old style couplers. The Precision Varicoupler is PERFECTION in receiving tuners. It has

No Taps	**No Sliders**
No Switches	**No Delicate Parts**
No "Dead Ends"	**All the Wire in**
No Contacts	**Use all the Time**



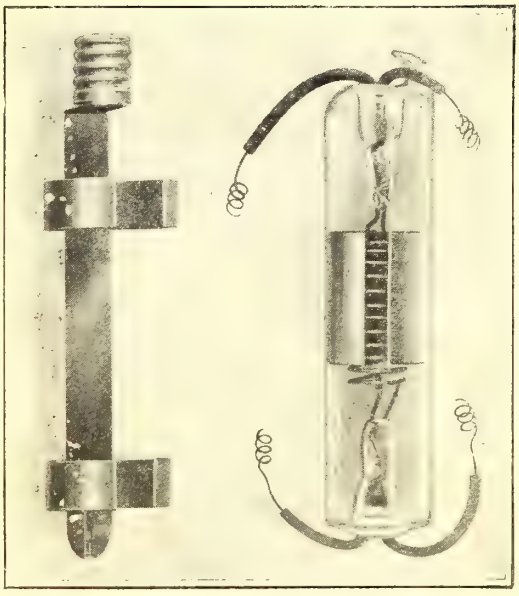
and is finished in mission oak, genuine cut hard rubber, silver finished wire, etc.

5 Styles, $10 to $25

For detailed information write for bulletin PL.

The Precision Radio Equipment Co., Inc.
General Office: 868 Putnam Ave., Brooklyn, N. Y.

LOOK! A NEW CHAMBERS COUPLER No. 744, PRICE ONLY $4.50



Positively unequaled for the money. Is 6" high, 6" wide, and 14" overall. Wound with Enameled wire, and has a very unique slider. Woodwork mahogany finished. Try one, you will not be disappointed.

5c. in stamps brings our 64-page illustrated catalogue, B-B-24. None otherwise.

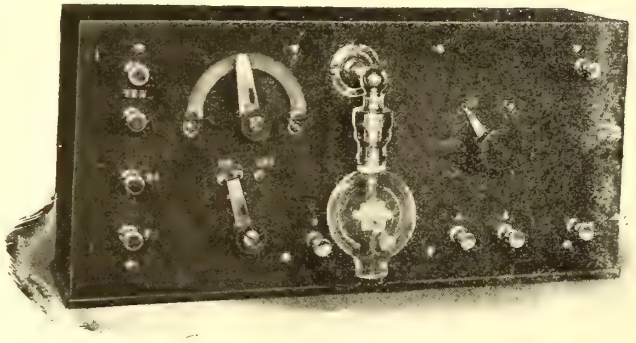
F. B. Chambers & Co. 2046 Arch Street Philadelphia, Pa.

The Great Announcement

THE NEW TUBULAR AUDION BULB will be sold SEPARATE from our instruments, taking effect March 15th.

This bulb brings in signals very loudly.
It has a single, straightline filament of very long life and is certain to be a very popular type. Made in one grade only, every bulb passing our usual and careful test.

To those who cannot afford our complete detectors with round bulb, this offer will be of immense interest.



Price—$5.50 each, postpaid, or from any of our 45 distributors.

The adapter illustrated above is not furnished with the bulb, but is 40 cents extra. It adapts the bulb to a regular screw socket.

ROUND AUDION BULBS will still be sold, as heretofore, as renewals only for De Forest instruments, and only on return of the old bulb.

NEW BULLETIN X16 on the type T, Tubular Audion Bulb, will be sent if you enclose stamp.

Type RJ8

PRICE, $25.00

New De Forest Audion Detector

THE BEST AUDION DETECTOR EVER OFFERED FOR PRIVATE USE

¶ The Audion Detector is the most sensitive detector in existence. (Bulletin U. S. Bureau of Standards, Vol. 6, No. 4, Page 540.) The new and improved forms are more sensitive, more reliable and more adaptable than ever before. The new Type RJ8 Audion Detector represents the greatest value for the money ever offered.

¶ It is equipped with **potentiometer** control for the high voltage circuit, giving extremely close regulation which is so essential to obtaining utmost efficiency with the Audion. It is a **panel type** instrument of the very best construction. It is thoroughly reliable and constant in operation, is not affected by mechanical vibration or by the transmitting spark, and is **always** to be depended upon for reception of signals over the greatest possible ranges.

¶ It is worth a stamp for you to be informed on this and the other new De Forest instruments.

"There is only ONE AUDION—the DE FOREST"

QUESTION BOX.

(*Continued from page 725.*)

tor, bearings too loose, short circuited segments, loose segments, overloading and overheating of the armature coils. Sometimes carbon brushes are gritty. Boil them in paraffine wax. Try carbon or graphite brushes with woven copper wire centers. Carbon brushes often have too high a resistance.

CONSTRUCTION OF PHONOGRAPHIC CYLINDERS.

(491.) James Fitzpatrick, Darlington, Pa., wants to know: 1. Whether a buzzer set operated by flashlight batteries can be used for exploding photographic flashlight powder? 2. How phonographic records are made?

A. 1. A buzzer set with sufficient amount of flashlight batteries and properly connected can successfully be used to explode the photographic flashlight powder.

A. 2. It would be impossible for us to go into the details of the construction of cylindrical phonographic records, as the process is somewhat complicated for explanation in our Question Department. However, we would say that a soft record plate is first produced and from this a metallic mold is built, in which all duplicates are made. We would advise you to write to several phonographic record manufacturers of this country and ask them to give you data as to the construction of their records. They may probably give you a general description of the method they use.

PHOTOGRAPHIC PLATES.

(492.) Francis Crump, Jr., Columbus, Ind., wants to know: 1. The chemicals used in making photographic plates. 2. The chemicals employed in manufacturing gaslight printing paper and how it is prepared.

A. 1. Photographic plates are made out of glass upon which a coating of gelatinous silver bromide is applied. The coating of this material is sensitive to light if applied in a darkened room.

A. 2. Gaslight printing paper is usually made with silver chloride in which a small trace of silver bromide is added. This material is mixed with a gelatinous compound and applied to sheets of paper.

WIRELESS IN FAR NORTH.

Wireless telegraphy will be used instead of the old poles and wire by the new Canadian Government Railway which is to connect Hudson Bay with the Canadian Northern at Le Pas, Manitoba.

A chain of wireless stations is already constructed between Port Nelson and Hudson Straits. When put into operation they will mark a new era in railroad telegraphy, for no other road depends solely on wireless over so long a stretch of territory.

There now remains only 100 more miles of grading to be done to complete the road bed from Le Pas to Port Nelson.

TUFTS COLLEGE HAS NEW HIGH POWER RADIO STATION.

(*Continued from page 700.*)

very latest design, wonderful testing instruments of a very delicate nature, and a perfect set of machinery for experimental purposes. The advantages in using only one aerial, according to Harold J. Power, head of the Atlantic Radio and Research Corporation, comes from the fact that the operators are better able to transmit messages to all points of the compass equally well.

The laboratory is practically sound and vibration proof, allowing the use of the most delicate testing instruments, a very important factor of the research work now being carried on there. Each room was carefully tested by Mr. Power with a microphone. The heavy machinery in the basement was turned on at full power, and not the slightest vibration could be detected in the room above.

On the northerly and westerly sides is the experimental laboratory well supplied with windows, so placed as to get the maximum light on the benches. In the machinery room the base, main shafting and pulleys are set solidly in the concrete floor, while the counter-shafting is bolted to a shelf, reinforced with steel brackets, so placed that rubber shock absorbers may be inserted between them and the floor if necessary.

A large assortment of the latest design testing instruments are to be found in this laboratory. These meters are so delicate that the minute current produced by placing the fingers on the contact buttons is recorded. The floors are all double and lined with heavy layers of felt. The doors are double soundproof. The Tufts Wireless Society will have a room in the building and eventually the plant will revert to Tufts College, together with all the costly instruments and machinery.

The credit for this addition to the electrical equipment of Tufts College, which has long been famous for the electrical engineers it has turned out among its graduates, and which was one of the first colleges in the country to take up radio research work, is due to Harold J. Power, a former student at Tufts and later a wireless operator on various steamers on the Atlantic.

Mr. Power started in wireless experimental work when wireless telegraphy was first being used on a commercial scale; Marconi, a few years previous, having published the results of his early experiments. Young Power, after weeks of hard labor, managed to construct a crude, but very complete wireless transmitting and receiving set. His "laboratory" consisted of a shack in the rear of his home. Little did he realize that 12 years later he was to sit down in a fine modern laboratory of his own and take down a message from Berlin, 4,000 miles away.

ELECTRICAL LOSSES IN TRANSMITTING AND RECEIVING SETS.

(*Continued from page 702.*)

frequent source of trouble. Ground connection should be made to moist earth only. If the earth around the station be sandy and dry, a *counterpoise* ground may be resorted to. This is made by stretching a wire netting similar, if possible, in shape and dimensions to the antenna just above the ground and insulated from it. The netting should be placed directly under the antenna to secure best results. Such a ground is used for military portable stations with very satisfactory results.

(*To be continued.*)

HOW TO ORGANIZE AND CONDUCT A RADIO CLUB.

(*Continued from page 699.*)

fecting himself alone. A member has a right to change his vote, if not by ballot, before the final result is announced, but not afterward.

ORDER IN DEBATE.

When a person wishes to speak he must rise in his seat, address himself to the chair, who must recognize him by name, thus giving him permission to speak. If several should arise at the same time the chairman must signify who shall speak first. No member should be allowed to speak more than twice, except to give a mere explanation, without special leave of the house, and the time a speaker may hold the floor is unlimited unless there is some rule of the organization limiting the speakers. If the chair rises to speak, the person standing must sit down until the chair has finished. In referring to another member it should not be by his name, but as "the previous speaker," "my opponent" or some such descriptive phrase. When a member is called to order he should sit down and not attempt to speak again until he has permission from the chair.

ORDER OF EXERCISE.

After an organization is effected the order of exercises adopted depends upon what is best suited for that body's deliberation. 2. Roll call. 3. Reading, approval, correction and adoption of the minutes of previous meeting. 4. Reports of standing committees. 5. Reports of special committees. 6. Unfinished business. 7. New business. 8. Communications. 9. Orders of the day. 10. Election of officers. 11. Reception of new members. 12. Announcements. 13. Adjournment.

PARLIAMENTARY DON'TS.

Don't attempt to discuss a motion until it has been stated by the chair.

Don't antagonize unnecessarily; nobody loves a barking dog even if he doesn't bite.

Don't be carried away in debate by a fervor or frenzy; moderation will win your cause most surely with reasonable minds, and your opinion will carry more weight. Speak slowly and distinctly.

Don't be too exacting to have the letter of the law enforced.

Don't forget that the common laws of politeness and respect due your fellow man obtain just the same in the society hall as in the drawing-room, even if the by-laws of the organization have no definite ruling on these points.

Don't cheapen your opinion in the eyes of others by speaking too often or upon every occasion. Keep quiet until you have something to say and a good reason for saying it.

Preface a motion with "I move that."

Don't leave it to the chairman to handle a motion relating especially to himself. The secretary or maker of the motion should state the question, put it to vote and announce the result.

PATENT ADVICE

Edited by H. GERNSBACK

In this Department we will publish such matter as is of interest to inventors and particularly to those who are in doubt as to certain Patent Phases. Questions addressed to "Patent Advice" cannot be answered by mail. Sketches and descriptions must be clear and explicit. Only one side of sheet should be written on.

WIRELESS DEVICES.

(50.) L. H. G. submits several ideas regarding rotary spark gap, quenched spark gap, hot-wire ammeter, and wishes to have our advice. He also wishes to know if, in case the devices are patentable, they could be sold for a reasonable sum without first obtaining a patent.

Our correspondent has an idea to increase the efficiency of a quenched spark gap by inclosing the entire gap in a certain gas, and wants to know if this would increase the efficiency of the gap.

A. A quenched gap will not work as well when inclosed in gas, for the reason that it will not be air-cooled as well as if it were under ordinary atmospheric pressure. For that reason it would work less efficiently.

On his rotary variable condenser a certain number of circular plates are mounted on two horizontal insulated rods. More or less plates can be placed in the circuit.

A. We do not see anything new in this condenser, as a similar one is already on the market, and the difference in the construction is not great enough to warrant your obtaining a patent.

As to the hot-wire ammeter, we believe its construction to be faulty, and we doubt if a patent can be obtained. As to the other question, we would never advise anyone to sell or offer for sale an invention without having first applied for a patent on same. It is a risky thing to do, and the inventor frequently loses the title to his invention.

EMPLOYES' INVENTIONS.

(51.) C. J. Conner, Coatesville, Pa., wishes advice on the following:

Can an employer, whether a corporation or individual, claim an invention made by one of his employes and patented by said employe, the latter not using the time or material of the employer when developing the invention, and further, the employe paying for the patent.

A. If the invention has not been developed on the premises of the employer he has no right to the patent, if obtained by the employe. Only by working on the employer's premises, using his tools and equipment, etc., can an employer actually claim title to an employe's invention. We would suggest that you write to a patent attorney and obtain detailed information on the matter.

NON-OXIDIZING CONTACT.

(52.) W. Rademaker, Hoboken, N. J., wishes advice on the following questions:

1. Having applied for patents on an absolutely water-dust-rust-fire-etc.,-proof nonoxidizing and unexplosive contact or circuit breaker, what would be, according to your opinion, its commercial value or field of application?

A. 1. It is impossible to say what the commercial value of the contact of this kind would be without knowing the composition of it. Just by having a contact fireproof means nothing, as some contacts are used under a very great heating stress where even platinum, which has a very high melting point, wears away in time. Tungsten is being used, as it has a very high melting point, but it is not very suitable on account of its being too brittle.

2. Are exposed circuit-making devices, such as rail, fire-alarm signals, bells outside, frequently inoperative on account of atmospheric influence, ice, sleet, etc.?

A. 2. Yes.

3. Are there any contacts on the market which work by a sliding member in an airtight space?

A. 3. To our knowledge there are quite a few such contacts on the market. We believe the idea is a common one.

NEW DETECTOR.

(53.) Carter Pietsch, Bloomington, Ill., submits a new scheme for a wireless detector which is supposed to operate by using certain metallic members and certain magnetic windings surrounding these members. Our correspondent wants to know if this detector will work, also if it is patentable. He also would like to know who the most reliable patent attorney is to whom he might submit the idea.

A. Without trying out a scheme of this kind it is wholly impossible to say offhand whether it would work or not. Would advise our correspondent to have a sample made up and tested, and if it works we think a patent can be obtained, for the idea is rather novel. As to patent attorneys, any patent attorney advertising in this magazine can be trusted implicity.

LOOSE COUPLER.

(54.) Oscar Taman, Chicago, Ill., submits drawing and specifications of a new long-wave loose coupler, and means are provided to entirely eliminate the dead end effect on long waves. Several moving tubes with wire are used in order to accomplish this. Inquirer desires to know whether his idea is patentable.

A. A loose coupler similar to the one you show is already on the market, and we do not think a patent could be obtained on your design.

Give the same thoughtful attention to the other fellow's ideas that you would have him give to yours, for in that way you not only learn more, but make more friends while you are about it.

PATENTS

IF YOU HAVE AN INVENTION which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention, and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of seventy years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand-Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to **Patents, Trade Marks, Foreign Patents,** etc.

All patents secured through us are described without cost to the patentee in the *Scientific American.*

HOW TO ORGANIZE A RADIO CLUB.

(*Continued from page* 728.)

THE CLUB LIBRARY.

While we do not wish to go on record as saying that books will teach everything, and further that we thoroughly believe in having every member of amateur clubs do some practical work with apparatus owned by the club or build some special instrument under the instruction of the club's instructor or engineer, yet we do wish to say that there is nothing more important for any such organization, whether large or small, than a good library. It may consist of six books or a hundred. At any rate, shortly after the club has been started on its mission the idea of forming a library should be promulgated and brought before the members. Besides books, a very important source of information is the magazines and periodicals available on the subject. These should be subscribed for at once, so that one or more copies will come to the reading table of the club each month.

The Electrical Experimenter is the leading wireless journal available to-day, and the following should also be subscribed for whenever possible: *Wireless World,* published by the Marconi Press Agency, Marconi House, Strand, London, W. C., England; *The Electrical World,* published by the McGraw-Hill Publishing Co., 239 West Thirty-ninth street, New York City, which very often publishes excellent engineering articles covering radio telegraphic developments of vital importance and interest to all live radio amateurs and operators.

The manager of the Radio League of America will be glad to advise anyone interested in this work as to where the best books, as well as the most reasonably priced ones, can be obtained on the subject of radio telegraphy and its allied branches. We give below a brief list covering the more important books on wireless furnished prepaid by the book department of *The Electrical Experimenter.*

LIST OF RADIO CLUB LIBRARY BOOKS.

Operator's Wireless Telegraph and Telephone Handbook. By Victor H. Laughter	$1.00
Wireless Telegraphy and Telephony Simply Explained. By Alfred P. Morgan	1.00

2 H.P. $35

Auto Throttle Governed Engine for Every Work

There is no other four-cycle engine with automatic auto type of throttle governor on the market near the price. Unlike ordinary low priced engines it is not hit-once-in-a-while governed with irregular speed and wasted gasoline.

It fires every shot with speed regulated by exclusive auto-throttle govenor which means even, economical power. It will operate electric light plant, pump water, run separator, churn or freezer, chop feed, operate machinery, in fact, it is "the engine for every work."

Hopper cooled complete ready to run, 2 H. P., for only $35. Direct to you from the factory. Write for catalog.

BOOK REVIEW.

SELF HELPS FOR THE CITIZEN SOLDIER. By Capt. James A. Moss and Capt. Merch B. Stewart. Cloth covers, 240 pages, profusely illustrated. Published by George Banta Publishing Co., Menasha, Wis. Price, $1.25.

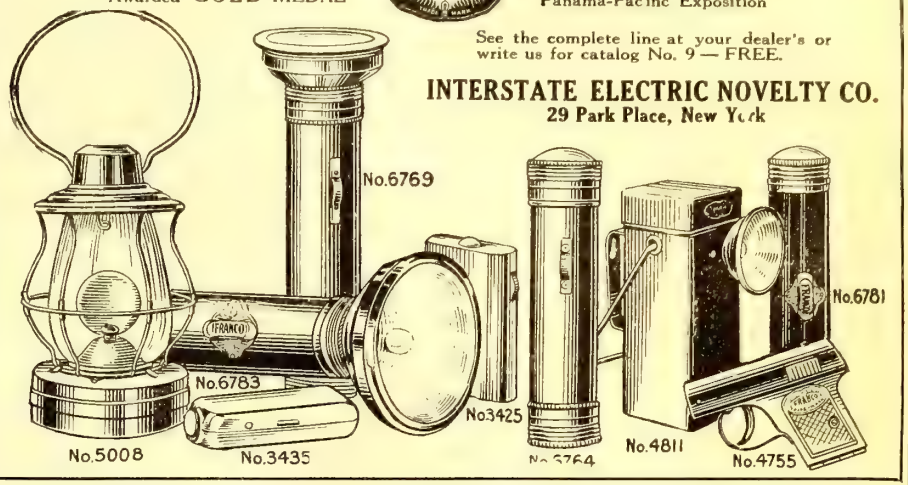
"We must depend in every time of national peril in the future as in the past, not upon a standing army, nor yet upon a reserve army, but upon a citizenry trained and accustomed to arms."

These words from President Wilson in his message, December, 1914, convey the thought of every thinking leader from Washington down to the present day. The present book is directly in line with such principles, and although it does not teach the citizen to be a soldier, it gives him information on the rudiments of what is required of soldiers, and by intelligent reading, he can clearly understand his duties and will fit smoothly into the military scheme.

The subject of our deficient defense receives attention in the forepart of the book, from which it goes on to explain the duties of a soldier. The book is well illustrated with photographs of soldiers in camp, on duty and at play. Pen pictures are used to caricature some false ideas and give the proper touch of light matter that relieves the seriousness of the book, yet brings home its importance in a very vivid manner.

Rules of hygiene and health are suggested to harden the citizen; full details of the National Rifle Association of America are given, as well as the rules under which arms and ammunition may be obtained without cost for rifle practise.

The planning and carrying out of a battle are described to impress upon the mind of the reader the importance of every man doing his best at all times, and how really important each cog is in a perfect machine.



The volume is written with a high ideal in mind by men who are working toward those ideals, and its true value may never be realized till the cessation of the present war leaves us rich, yet unprotected, while the foreign coun-

You Ought to Have the Best Flashlight

When you are coming home late at night, or working around the house and need a light, you want a light that will *stay* lit and won't start fires.

Here's YOUR Chance to Learn
DRAFTING
This Complete $15 Drawing Outfit and Full Instructions in Mechanical Drawing FREE

There's a good job waiting for you. The country is facing greater prosperity than it has ever before experienced. Far-seeing men are getting ready for boom times. Get this training now and share in the coming prosperity. We make the way plain.

CHARLES W. MOREY
President of the College and Head of a Large Chicago Firm of Civil, Mechanical and Electrical Engineers and Contractors.

Men Wanted
AT BIG SALARIES

This is a rare chance for a few wide-awake young men.

On account of the rapidly increasing demand for trained draftsmen Pres. Morey has issued orders that instructions be furnished to a limited number of young men who are inclined along engineering or architectural lines. Read about this great offer below—then mark and mail the coupon.

STUDY AT HOME Devote your spare hours for a short time only and learn this profitable and pleasant profession, and get in the class drawing the big pay envelope. Hundreds of men are in daily attendance at this old established college. In your own home you can do the same work these men are doing, and the same experts that teach them will guide you toward the big job. These well-known engineers prepare your instruction matter. Your work is examined and approved by them. They know exactly the practical training you need and they train you. No books to sell. Live, up-to-date blue prints of work in actual construction. In your own home you work with plans of machinery, buildings, steel works, etc., actually being constructed in Chicago, New York and other large cities.

Electrical Drafting and Design

No other similar correspondence course in America has a resident college of National reputation back of it, nor a faculty of active experts actually engaged in municipal and corporation engineering work. These men know exactly the kind of training you need because they are in constant charge of big work.

$45 COURSE FREE
IN MECHANICAL DRAWING

This College has set aside a limited number of Free Scholarships and will give the regular $45 Course in Mechanical Drawing Free with any one of the Home Study Courses named in the coupon below—this is in addition to the complete $15 Drawing Outfit which is also furnished to students free. Take advantage of this unusually liberal offer today, as it will be withdrawn when the allotted number of Free Scholarships has been awarded. It costs you nothing to get full information. No obligation on you.

CHICAGO TECHNICAL COLLEGE
1060 LAKE VIEW BLDG. CHICAGO, ILL.

tries will be poor and in debt, but equipped with a mighty war machine that can only be met with men who handle a rifle as well as they do a cane.

The Radio League of America was formed with a similar idea of preparedness in mind. This book will be of great service to members of the League who realize their duty to the country in time of peril, enabling them to grasp clearly the part they will have to play in the mighty drama of war, should this harbinger of sorrow ever visit our fair land. It is a step in the right direction and the only criticism is that many more and interesting details might be incorporated in its make-up.

THE ELEMENTARY PRINCIPLES OF WIRELESS TELEGRAPHY. By R. D. Bangay. Cloth covers; 7⅜x5 inches; 155 pages; 86 illustrations. The Marconi Publishing Corporation, New York City. Price, 35 cents.

Amateurs, as a class, have been waiting for such a book. It contains no "how-to-make-it" or construction data on apparatus, but confines itself to a clear and lucid explanation of high frequency phenomena in its relation to wireless telegraphy.

The reader will marvel at the ease with which the writer takes him through the book, explaining the operation of the different apparatus used in a manner not made tiresome by reiterations, useless words or flights of fancy so often indulged in to make a book imposing.

The elementary phenomena of electricity and magnetism is dealt with but only in so much as it refers to the subject on hand, and the student quickly picks up the theory of the art.

All of the apparatus used at the present time is explained in language that is concise and untechnical.

HANDBOOK OF TECHNICAL INSTRUCTION FOR WIRELESS TELEGRAPHISTS. By J. C. Hawkhead; revised by H. M. Dowsett, A.M.I. E.E. Cloth covers; 5¾x7¾ inches; 295 pages; 242 illustrations. The Marconi Publishing Corporation, New York City. Price, $1.50.

The vast number of Marconi stations on shipboard and the many recent improvements in same has made necessary a revision of this work as originally written by Mr. J. C. Hawkhead. The aim of this treatise is to put into the hands of the ship radio operator a book that will be of assistance in giving him a solid foundation on which to base phenomena noted in practical work.

The suggestions incorporated in the book are not only of use to the commercial operator but could be followed with profit by amateurs interested in having up-to-date and efficient stations.

All types of apparatus used by the Marconi Co. are portrayed and explained, both the care and operation up to and including the multiple type tuners and 5 K. W. transmitting sets.

Quite a large amount of space is allotted to the explanation of elementary electricity, thereby forming a solid basis for other information included in the work.

LIST OF RADIO STATIONS OF THE WORLD. By F. A. Hart and H. M. Short. 220 pages; 8¼x5½ inches; cloth bound; 35c. Supplied by The Experimenter Publishing Co., New York City.

This book is divided into four parts and arranged so any operator may easily and quickly locate the call of any station desired, or on the other hand, just as easily determine the name and position of any station sending a call that is heard through a wireless set.

The first part lists all radio stations of the world, land and ship, alphabetically by their calls and this list is corected up to May, 1915. By means of this list it is possible to trace any call to the station of its origin.

The second part lists naval stations alphabetically by country and vessel, while part three lists commercial ship stations by vessels, giving owner, nationality and control.

The last section contains a list of coast stations, arranged alphabetically by country and station.

The book is printed on high-grade paper in large, easily read, type and is a valuable addition to any radio station, commercial or amateur. Being practically indispensable when accurate data is required for calls heard or stations that are to be communicated with, and still within the reach of every one, it should find a ready demand.

X-RAY INDISPENSABLE.

Electricity is extensively used in modern surgery. Indeed, it would be difficult to get along without it. Without the X-ray machine it would be impossible to accurately locate foreign substance in the body. X-ray photos are also extensively used in diagnosing a large number of other ailments, such as tumors and cancers.

We Guarantee First Grade Commercial Operators' Licenses

THE CHEMISTRY OF THE STORAGE BATTERY.

(*Continued from page* 711.)

either in the plates themselves or in the electrolyte, these normal reactions may be departed from. The impurities which may damage a battery are of three kinds:

IMPURITIES.

First—Foreign metals, or salts of such metals, especially such as are less electro-negative than lead, i. e., copper, silver and platinum. They are immediately precipitated on the negative plate and form, with the negative active material, innumerable points at which local action takes place. The spongy lead is, by this action, converted into lead sulphate, free hydrogen gas being evolved at the foreign metal. This action is greater the greater the quantity of metallic impurity and the more readily hydrogen gas is thrown off its surface. Platinum is the worst of the metals in this respect. A familiar example of this action is the following: Chemically pure zinc is but very slowly attacked in dilute sulphuric acid. On the addition of a mere trace of copper sulphate, copper is precipitated on the zinc, creating local action, and the zinc is violently attacked with the evolution of free hydrogen gas.

Second—Metals such as iron or manganese, whose salts are readily oxidized or reduced. Iron or ferrous sulphate is, for example, readily oxidized to ferric sulphate in contact with lead peroxide, while the ferric sulphate is again reduced to ferrous sulphate in contact with the spongy lead, each of these actions being accompanied with loss of charge of the corresponding plate and the formation of lead sulphate. A considerable quantity of iron or manganese will rapidly discharge a battery in this way.

Third—Foreign acids or salts of these acids or acid-forming substances. The effect of these substances is a rapid corrosion of the grids. The presence of such acids, even in minute quantity, must be avoided.

It is on account of the above actions that care should be taken to use only such acid and water as are known to be pure.

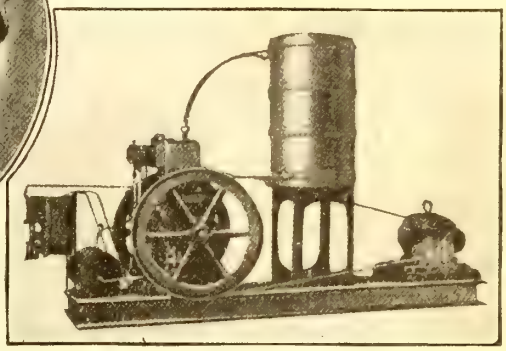
PUPIN'S NEW NON-INTERFERENCE ANTENNA.

(*Continued from page* 701.)

quency higher than a given range of frequencies. The station becomes then an ear which is quite sensitive for frequencies which are in the vicinity of the signaling frequency, but which is stone deaf to frequencies which are considerably beyond the range, as most static disturbances are. Similarly, a sectional wave conductor can be constructed which is quite responsive to frequencies in the vicinity of the signaling frequency, but absorbs almost completely everything below this range. My theoretical and experimental investigations encourage me in the belief that a perfect barrier has been found against disturbances due to the so-called static, and that the distances of uninterrupted wireless telegraphy and telephony will be very greatly increased.'

RECTIFICATION NOTICE.

We are advised by Casimir Jaroszewicz, who recently submitted a contribution for the monthly station contest in the February, 1916, issue of *The Electrical Experimenter*, that the radio set there described over his name is owned by Harold Burbridge, 6109 South Green street, Chicago, for which party Mr. Jaroszewicz prepared the article.



A Continuous and Cheap Service of ELECTRIC LIGHT

In Your Country Home, Hotel, Club, Church Institution or Small Town

You simply switch on or off your lights and the

BRUSTON PLANT

Starts Itself
and
Stops Itself

OVER 1,000 IN USE

THE BRUSTON AUTOMATIC ELECTRIC LIGHTING PLANT gives you the same continuous service of light and power in your country home, hotel or institution as you have in the City of New York.

The plant is absolutely automatic, starts itself, regulates itself and stops itself. Practically the only attention required being to fill the fuel and oil tanks.

It will generate current at less than half what it would cost you in the city.

This plant has obtained the highest awards at the leading expositions in England, Canada and France, has been installed in the houses of many of the leading people of the world and has never been replaced by another plant or taken out as unsatisfactory.

Send for catalogue "X" or call at our office and see a plant in actual operation

New 1916 Edition of "Experimental Wireless Stations" by Philip E. Edelman

Now ready. Enlarged to 272 pages with new illustrations

Greatest offer in wireless books. Only volume that is up to date for 1916. Contains all the 1914 edition and, in addition, gives full information on Audion Amplifiers, Pliotron, Cascade Amplifiers, Audion Oscillator and Ultraudion. Receiving set for long wave and undamped wave reception. Tuners and couplers of all sizes up to 14,000 meters, circuit used for transcontinental telephony from Arlington, Va. Railroad, Automobile and Aeroplane Wireless. Latest information on receiving time and weather signals. Dimensions of aerials for all wave lengths. Wireless Compass, Heterodyne Receiver. Use of Crystal Detector with Audion, etc. Tells how to receive 4,000 miles with a small aerial, about ground aerials, dead-end switches, telemechanics with audion circuits instead of coherers. How to find the trouble when a set won't work. Lieben-Reisz Amplifier, etc.

This 1916 edition contains a complete classified list of all the U. S. Patents granted for wireless telegraphy, telephony, and control from the beginning to date, together with a discussion of the more important recent patents. This gives the key to the entire art and no experimenter can afford to be without it.

This book has the highest recommendations of radio engineers, wireless experts, radio inspectors, wireless associations and operators.

Owing to large increase in size and expense, a higher price is contemplated, but on orders received immediately, the new 1916 edition will be supplied at the previous low price of only $1.50. If you have the old edition you will want the new. NOW!

Send $1.50 and 15c. postage at once. Book will be sent by return mail. Satisfaction guaranteed.

P. E. EDELMAN Publisher 1802 Hague Ave. St. Paul, Minn.

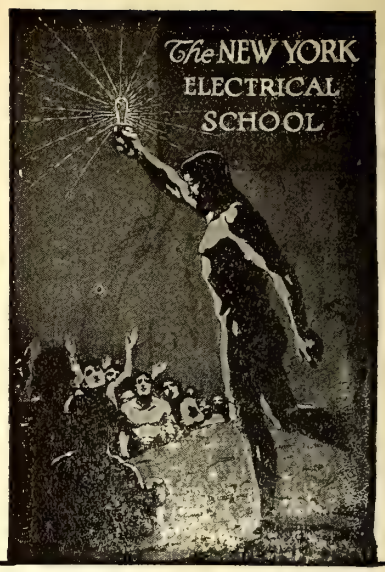
PLATING QUARTZ FIBERS BY A CATHODE SPRAY.

The construction of many sensitive electrical instruments necessitates having a conducting support which shall be very light, besides having a constant torsion. This usually takes the form of a quartz fiber and many schemes have been used to render this substance a conductor, among which can be mentioned the method of spraying metallic particles on the fiber proper by mechanical means and also by electroplating platinum on the fiber.

Advantage was taken of the cathode discharge noticed in connection with Crookes' tubes in devising a new method of plating quartz fibers, which requires more or less extensive apparatus, but the illustration herewith gives a good idea of the process. An aluminum or glass tube is shown at A which has a rather thick wall. In the bottom is sealed a pipe P which is attached to a vacuum pump of any desired type, but it must be powerful enough to create a high vacuum in the chamber. The plug B in the upper end is ground into its seat to make an air-tight joint, and vaseline is used to seal this joint. The center of the plug is hard rubber surrounded by a ring of brass,



Apparatus Used to Plate Quartz Fibers by a Cathode Spray.

while through the center of it passes the rod R. Supported from the lower end of the rod R is the fiber which is to be plated with platinum. This fiber is kept taut by the weight W. At N is shown a sheet of the platinum foil which is fastened to the side of the cylinder if the tube is of aluminum. Should the tube be made of glass a platinum wire is sealed into the glass to make connection to the foil.

In operation the device acts in the following manner: Hydrogen is admitted to the chamber and the vacuum pump is then started, which creates a rarefied atmosphere of hydrogen. The terminal X in the plug is connected to the positive pole of the induction coil or transformer and the terminal Y is connected to the negative pole. When the coil is in operation according to the phenomenon taking place in a Crookes' tube the cathode rays will be thrown off from the tube toward the center. If the tube is made of aluminum there will be very little, if any, aluminum deposited on the fiber, whereas the platinum foil will have fine particles torn off and forcibly deposited on the quartz.

It is advisable to turn the plug at frequent intervals, so that all sides of the fiber will be acted upon by the platinum. This turning of the plug may be eliminated by coating the entire inner surface of the cylinder with platinum, but this makes the apparatus much more expensive to construct.

The resulting film of platinum on the fiber will be found to be very coherent, thin and of comparatively low resistance.

THE N. Y. ELECTRICAL SCHOOL is the pioneer and premier school of the "Learn by Doing" method. When you have completed this Course you shall be fully qualified to handle ALL branches of Electrical industry.

The equipment of this School is unequalled and up-to-the-minute. No preparation needed to become a "learner" in this school. You can start to learn on any day of any week throughout the whole year. Send for catalogue.

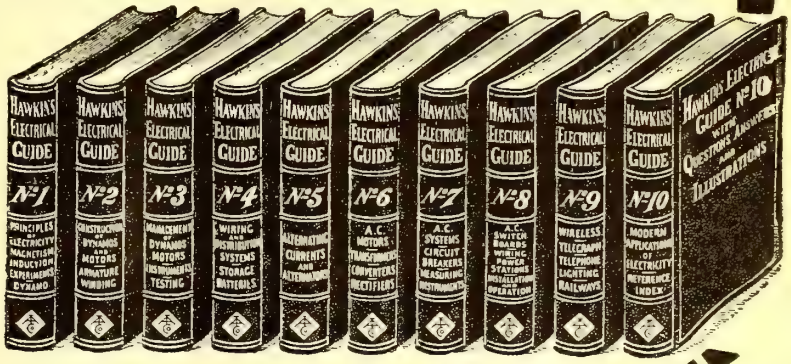
"For the man not getting a college training and even in that case, I can sincerely say I do not believe there is a better set of books in the market today." LLOYD D. HUFFMAN
Dayton, O.

"We consider Hawkins Electrical Guides the most compact and complete set of electrical references in the market."
NOGGLE ELECTRIC WORKS
Monterey, Cal.

"Hawkins surely knows the art of condensing information." ELBRIDGE F. BALL
Buckland, Conn.



Hawkins Electrical Guides Will Show You How

These books are the standard works on Electrical Science. They are a complete and up-to-date course in Electrical Engineering, presenting the information in a way you can use it. Only $1.00 per volume and owners of the set say there are no better electrical books published at **any** price.

Specially Arranged for Home Study and Reference They fit your pocket and your pocket book. Beautifully bound in **flexible** black leather with gold edges. Easy to read and handle. You can carry each single volume about with you until you have mastered the subject it contains. Written in the form of questions **you** would ask and the answers to them — in plain, practical, everyday language, complete, concise, authentic and to the point. Over 3200 pages and more than 4,000 illustrations.

10 NUMBERS IN ALL

1.00 A Number PAYABLE 1.00 A Month

Shipped to You FREE

Send no money. Examine the books first. Decide for yourself that they are the most complete library of Electricity ever published and that you cannot afford to be without them. Every book is complete in itself, but the complete set is the best bargain. The last volumes are just coming off the press. **Eight numbers now ready.**

Easy Payments

Accept this unusual offer now — today. Each page—every illustration will convince you of the big value we are offering. See the books first, then decide. If you decide to keep them you can make settlement at only $1.00 monthly until paid for.

A FEW OF THE SUBJECTS

Magnetism—Induction—Experiments — Dynamos —Electric Machinery—Motors—Armatures—Armature Windings—Installing of Dynamos—Electrical Instrument Testing — Practical Management of Dynamos and Motors—Distribution Systems—Wiring—Wiring Diagrams—Sign Flashers—Storage Batteries—Principles of Alternating Currents and Alternators—Alternating Current Motors—Transformers—Converters—Rectifiers—Alternating Current Systems—Circuit Breakers—Measuring Instruments—Switch Boards—Wiring—Power Stations — Installing — Telephone — Telegraph — Wireless—Bells—Lighting—Railways. Also many Modern Practical Applications of Electricity and Ready Reference Index of the 10 numbers.

MARVELS OF MODERN PHYSICS.

(*Continued from page* 698.)

region of the ultra-violet than in that of the infra-red. These are the waves which often prove harmful to the eyes, but on the other hand their great germicidal power has been successfully harnessed by a Danish physician, Finsen, who achieved remarkable success in the treatment of skin diseases and cancer with them. In medical circles the name *Finsen Rays* has been given to the ultra-violet rays used by him.

The production of ultra-violet light is simple. The ordinary arc light is rich in it, but as ordinary glass cuts off these rays, the globe is generally made of quartz.

So far we have said nothing about the X-ray or the invisible radiations given off by radio-active substances, because this is where we come in contact with the other great class of invisible radiations, consisting of fine, rapid-moving particles of matter, and it was long a mooted point as to which class X-rays themselves belonged.

The Crookes' tube was one of the first vacuum tubes to be used in connection with electric discharges. It consisted of a bulb-shaped tube and two electrodes, as in Fig. 3. Plücker discovered the fact that certain rays were given off at the cathode, and these were found to be minute particles having a *negative* electric charge. Later Goldstein discovered the canal rays, or rays given off at the anode, which travel much slower and are *positively* charged. Not until 1895 did Röntgen discover that still other rays were given off at the anode, and on account of their unknown character he termed them the *X-rays*. On account of the fact that they could neither be refracted, reflected nor polarized he thought them to be different in nature from light waves. It is known now, however, that ether waves may be either periodic trains of waves or irregular pulses, very short, and that irregular pulses may not necessarily be subjected to the laws governing ordinary periodic trains. Consequently it seems quite well established that the X-rays are very short, irregular, transverse disturbances in the ether caused by the electrons bombarding the positive target in the tube. It is further thought that the X-rays, on account of their length, should be placed about the ninth octave above the visible spectrum.

As for the radio-active substances, of which uranium is one of the most active, the invisible radiations are quite similar to those of the X-ray tube. These emanations were originally called Becquerel rays, after the scientist who first noticed them. However, instead of one, there are three distinct kinds of rays, known as the alpha, beta and gamma rays (α, β, γ). These *alpha rays* consist of a stream of positive particles, while the *beta rays,* which are more penetrating, are identical with the cathode rays mentioned before. The *gamma rays* are extremely penetrating, and appear to be quite similar to X-rays.

Thus it is seen that the invisible radiations of the radio-active substances are composite. The remarkable feature is that they originate spontaneously and that though they may be given off for a long period of time the action does not seem to materially decrease. In order to aid in distinguishing between the different rays they are shown diagrammatically in Fig. 4.

One more interesting phenomenon in connection with invisible radiation is the property of certain substances known as *fluorescence.* Such substances are really light transformers; that is, they transform invisible waves to such lengths that they are visible. Beautiful color effects can be obtained by throwing ultra-violet light on such substances.

One of the most important results of the present-day study of invisible radiations is the bearing these results have on our theories of the ultimate constitution of matter. In the case of radio-active substances the atoms are unstable and the radiation goes on at the expense of the internal energy of the atom. The question arises, why should these atoms be so unstable? Is it an electrical phenomenon?

And we are, of course, brought again to the problem of the electro-magnetic wave. Experiments of the past year seem to indicate that the X-rays themselves may be reflected, refracted and partially polarized, and this develops still further the idea of the similar nature of all ether waves, although there still remain several striking differences between X-rays and light rays.

The development of the electron theory of matter has largely been an outgrowth of research in radiation. We know that the velocities of the alpha, beta and gamma rays are widely different, the speed of the first being about 20,000 miles per second,

LIGHTNING, ITS EFFECTS AND HOW TO AVOID THEM.

(*Continued from page* 683.)

thing like sharp bends around cornices and projections.

The number of conductors necessary depends on the size of the building and the comparative heights of its structural parts. There is no special area below an elevated rod which can be considered as actually protected; so that "area of protection" really cannot be defined, and no definite rule can be laid down as to the number of rods necessary to protect a building. The consideration of the extent of protection afforded must bear some relation to the value and importance of the building concerned. It should be the practise to provide at least two or more rods on any building. The best known system of protection is that referred to before.

It should be noted that any chimney stack is liable to be struck; each, therefore, should have its own elevation rod connected to the nearest conductor leading to earth. Special attention should be paid to kitchen chimneys, as a column of hot air will often be selected as a path for the flash.

The earth connection should be made either by means of a copper plate buried in damp earth, or by the tubular earth system, or by connection to the water mains. The number of connections should be in proportion to the ground area of the building, and there are few structures where less than two are necessary; if it is thought desirable to use the modified "bird-cage" system, described heretofore, each side of the building should have its own earth. Church spires, high towers, factory chimneys, etc., having two ground conductors should have two earths, which may be interconnected.

If a copper plate is used it should not be of less than 3 sq. ft. in area and not less than ¼ inch thick, rectangular in shape, with saw-tooth edges and surrounded with broken coke or graphite. If coke is used, it must be thoroughly washed to eliminate any sulphur which may destroy the copper. The conductor should be firmly attached so as to make a permanent mechanical and electrical joint.

MARVELS OF MODERN PHYSICS.

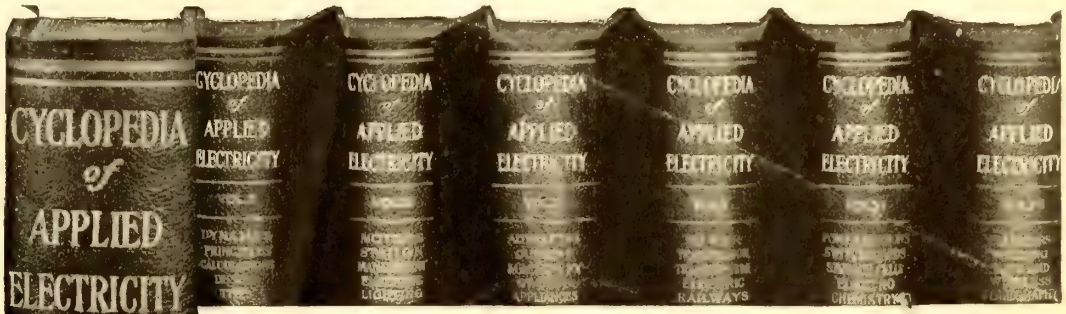
(*Continued from page* 736.)

the second 100,000 miles per second, and the third 186,000 miles per second.

This is a step toward the solution of the riddle of modern physics, which resolves itself into the question as to what is the finite nature of positive and negative particles and electro-magnetic waves.

[This is the third paper of a series prepared especially for The Electrical Experimenter by Mr. Rusk.—EDITOR.]

A 500,000-VOLT TESTING TRANSFORMER.



The Oerlikon (Switzerland) Works regularly manufactures testing transformers giving voltages of 200,000 and 250,000. For use in their own laboratories they have found it necessary to construct a transformer yielding in normal operation a difference of potential of 500,000 volts. The exterior shape of the apparatus is cylindrical, 3.3 meters in diameter and 3.6 meters high. Its total weight is 34 tons. It is capable of taking a current of 1,000 amperes at 500 volts. At 500,000 volts the sparking distance is 1.32 meters, and at its maximum overload, giving a voltage of 700,000, the sparking distance is 1.85 meters.

DO YOU

own a wireless station, either for sending or receiving? If you do, don't fail to join the greatest Wireless Association in the country: THE RADIO LEAGUE OF AMERICA. If you believe in the preparedness of your country, if you wish to help Uncle Sam, if you wish to have your station **officially** recognized, join the LEAGUE, a national, non-money-making organization. Beautiful engraved and sealed certificate, FREE to all members. NO DUES OR FEES WHATSOEVER.

Honorary Members: W. H. G. BULLARD, U. S. N.; PROF. REGINALD A. FESSENDEN; DR. LEE DE FOREST; DR. NICOLA TESLA.

This Great Electrical Library SENT FREE FOR EXAMINATION

Send today for your free-for-examination set of the greatest electrical reference library of modern times. The new 1916 edition, just off the press, is recognized by big men in the electrical field as the most practical work of its kind ever published. Covers completely the generation and use of electricity for power, light, transportation and communication, including the construction and operation of dynamos and motors, central station engineering and telephone work, as well as **wireless telegraphy and telephony** and land and submarine telegraphy. Particularly helpful in its exhaustive treatment of electrical "troubles" and their remedies.

Earn $150 to $250 Monthly Electrical Engineers earn from $150 to $250 a month. The work is pleasant—the hours short. These great books will fit you—**In your spare time**—to enter this fascinating, high-salaried work. No previous experience necessary.

Cyclopedia of Applied Electricity

Contains 3,500 pages, 7x10 inches; 3,000 illustrations, full page plates, diagrams, etc.; hundreds of valuable tables and formulas; carefully cross-indexed for quick, easy reference. The books are substantially bound in half red morocco, gold stamped, and are printed in large, clear type on special quality paper.

What These Books Cover

Elements of Electricity — Electrical Measurements — Underwriter's Electrical Requirements—Theory, Calculation, Design and Construction of Direct Current Generators and Motors—Types of Generators and Motors—Management of Electrical Machinery — Electric Lighting — Alternating Current Machinery — Power Transmission — Electric Railways—Self-Propelled Railway Cars — Trackless Trolleys — Power Stations — Switchboards and Switching — Storage Batteries — Applied Electrochemistry — Electric Elevators — Electric Welding and Heating — Wireless Telegraphy and Telephony—Land and Submarine Telegraphy.

50c a week The complete seven volumes, not a sample volume, will be sent, express prepaid, for seven days' free examination; returnable at our expense if they fail to meet with your expectations. If you keep them, pay $2 seven days after receipt and then $2 a month until you have paid the special introductory price of $19.80, saving $15.20, as the regular price of this new and enlarged edition is $35.00. As this offer is for immediate acceptance only, fill in and mail the coupon today. It won't cost you a cent to examine these books, so get them into your home, shop or office and look them over at your leisure. Remember, if you don't like them they may be returned at our expense and you won't be out a penny. One of the most liberal offers ever made. You can't afford to pass it by.

Consulting Service Free With every set is included absolutely free a year's Consulting Membership, regular value $12, entitling you to the advice of a staff of electrical experts. These men are no further from you than your nearest mail box. They stand ready to solve your perplexing problems, to offer suggestions, to point out the things you should avoid. Absolutely no limit to their assistance—ask as many questions as you wish for a whole year. This service alone will be worth more to you than the entire cost of the books.

Don't wait. This means $15.20 saved if you act now. Remember, you take no chances whatever—it costs nothing to inspect and you are nothing out if you do not care to buy. This offer may mean your success, so mail the coupon today—**now**—before you turn the page.

You Can Get Better Results

BY USING THESE WONDERFUL BOOKS

How to Make Wireless Sending Apparatus

This book will surely be welcomed by every wireless enthusiast, and by the one who is fond of making his own apparatus. This book contains more information on how to make sending apparatus than any other book we know of. Thirty different pieces of apparatus can be made with materials that most anyone can obtain without much trouble and illustrations and descriptions are so clear and simple that no trouble will be experienced in making the instruments.

Only strictly modern and up-to-date apparatus are described in this book, and if we asked you 50c for it, we are sure that you would think it a bargain. This book has been written by twenty radio experts who know how to make wireless sending apparatus and for that reason you profit by their experience as well as by their experiments.

Among others, this book contains the following important apparatus: How-to-Make an Experimental Arc Set, How-to-Make a Speaking Arc Light, How-to-Make a Quenched Spark Gap, How-to-Make a ¼ K. W. Transformer, How-to-Make an Oscillation Transformer, How-to-Make a Radio Break in System, How-to-Make a Photophone, How-to-Make a Rotary Spark Gap, How-to-Make an Independent Vibrator, How-to-Make a Calibrated Spark Gap, and many others.

Size of the book is 7 x 5 inches, substantially bound in paper; the cover being printed in two colors. There are 100 pages and 88 illustrations. There are quite a few full-page illustrations giving all dimensions as well as photographs showing finished apparatus.

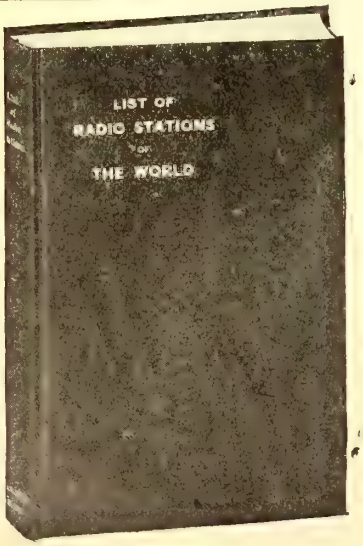
25c PREPAID

How to Make Wireless Sending Apparatus,

How to Make Wireless Receiving Apparatus

This book will surely be a boon to every "how-to-make-it" fiend. It has been written and published entirely for the wireless enthusiast who makes his own receiving apparatus and the twenty radio constructors who have written the articles are well-seasoned in the art and know whereof they speak. Consequently, you profit by their experience.

Only strictly up-to-date and modern apparatus are described and only those that the average experimenter can make himself, with material that can be readily obtained. We believe that **this book contains more information on how to make a wireless receiving apparatus than any other book in print** and you will find that it is easily worth double the price we are asking for it.



Among the many good articles, the following will be of particular interest: How-to-Make a Receiving Set Without Aerial or Ground, How-to-Build a Magnetic Detector, How-to-Make a Wireless Relay, How-to-Make a Wireless Lecture Set, Intensifying Radio Signals, Construction of an Improved Loose Coupler, How-to-Make a Conical Tuning Coil, Construction of an Interference Preventer, How-to-Make a Unique Receiving Transformer, Construction of an Efficient Wave Meter, How-to-Make a Pocket Wireless Set, etc., etc.

Size of the book is 7 x 5 inches, handsomely bound in paper; the cover being printed in two colors. There are 100 pages and 90 illustrations. There are quite a few full-page illustrations giving all dimensions as well as quite a few photographs showing the finished apparatus.

25c PREPAID

How to Make Wireless Receiving Apparatus,

Thousands of dollars were gladly spent to compile this book NOW OFFERED to you for the unusual price of . . 35c Postage on 1 lb. extra

CONTENTS

Tells you quickly and accurately either call letter or station name and location of **any** and **every wireless station in the entire World.** Obviates that irritating moment when you hear an unknown call and have no means of quickly knowing who it is. Makes it worth while sitting up late at night to hear that faint and far off foreign call, for with it, at least, you can tell whom you hear. **Contains 222 pages of information worth its weight in gold,** lists over 15,000 ship and shore stations by **BOTH** nationality, location and call letter being cross indexed to give location, ownership and station designation.

A REALLY REMARKABLE OFFER

Imagine a finely cloth bound book 5½ x 8½ inches and ⅞ inch thick in size, containing 222 pages of information obtainable nowhere else and printed on an excellent grade of book paper and from type unusual for clearness and ease of reading. Not only is it up to date, but provides means for the insertion in their proper places of newcalls of **every nationality** whenever assigned. Positively the best work of its kind ever offered and **WORTH $2.00 PER COPY.**

HOW IT IS POSSIBLE

This remarkable offer is possible only because of the financial difficulties which prevented the publishers from marketing a book which cost them thousands of dollars to compile alone, while thousands more were spent in editing, composition, printing and binding. Being exhausted the printers came to us as the logical outlet and we offer you these books at a price less than they actually cost to produce.

AUTHORS

The book was compiled by **FRANK A. HART, Chief Inspector of The Marconi Wireless Telegraph Co., of America,** and **H. M. SHORT, resident Inspector (U. S. A.), Marconi International Marine Communication Co., Ltd.** Need we say more as to the authority which these men have at their command to compile so noteworthy and necessary a book?

DELIVERY

We have on hand a very limited number only of these books and **NO REPRINTS WILL BE MADE.** We cannot, therefore, urge too strongly that you send in your order at once. All orders will be filled in the order of their receipt. Better **send for it TO-DAY** and make sure of getting the greatest book value possible to get. When you get the book you will say we've underestimated the value we offer.

NOTE! POSTAGE IS EXTRA ON A SHIPPING WEIGHT OF ONE POUND. So include sufficient postage with your remittance which should be in cash or by money order.

EXPERIMENTER PUBLISHING COMPANY, Inc., BOOK DEPARTMENT, 233 Fulton Street, New York, N.Y.

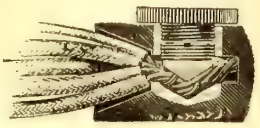
ELECTRICITY KILLS PROMINENT WIRELESS MAN.

On Feb. 4 last Virgil J. Simpson, one of the foremost wireless men of St. Louis, Mo., met his death in the radio laboratory of the Christian Brothers College of that city.

Mr. Simpson had gone to the laboratory to conduct a radio test on a new 5-kilowatt transformer of his own design and which he had just completed. He proceeded to check up the calculations by connecting a step-down potential transformer to the secondary terminal of the large step-up transformer, which latter yielded 10,000 volts. The voltmeter was connected across the low potential or primary winding of the small potential transformer usually employed for such voltmeter readings. The accident happened while he was attempting to disconnect the test instrument from the larger apparatus, forgetting for a moment that he had not opened the main primary switch connected with the 10,000 volt transformer.

The 10,000 volt current, although of not very heavy amperage, passed through his body for some seconds before he managed to jerk away one of the leads. A companion rushed to his aid and reached his side just as the victim freed himself from the charged wire. They walked to the middle of the laboratory, but the shock had been too much for him and he collapsed. Physicians were immediately summoned and worked over him for about an hour with a pulmotor, but to no avail.

His death should be a caution to all electricians, and particularly to those in the radio field, never to attempt to make connections in high tension transformer circuits until the primary circuits are opened. A moment's carelessness, as in the case of Mr. Simpson, may spell death.

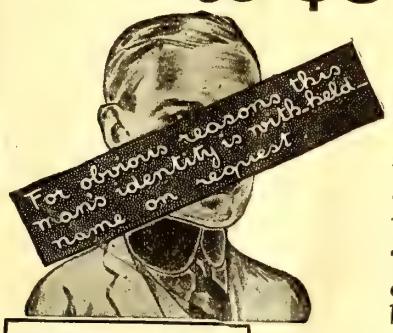


A PECULIAR ELECTRICAL ACCIDENT.

An odd electrical accident is reported in a technical paper on "Safety in Stone Quarrying," recently issued by the Bureau of Mines, Washington, D. C. A transformer supplying a stone quarry burned out, permitting 4,000 volts to pass to the hoisting motors. The man in charge placed his hand on the lever and as the machine was electrically charged he could not let go. As he was wearing rubber-soled shoes he sustained no injury. He called for help and the man who came to his assistance, instead of pulling the switch and cutting off the current, took hold of the engineer's hands and tried to pull them free and in so doing completed the circuit and was killed. The man with the rubber-soled shoes was unharmed except for slight burns.

Seventy per cent. of the people use electricity in some form every day. Most of us use it in some form during the month.

A NEW INSULATED CONNECTOR.



In the past the most troublesome thing about wiring has been the soldering of joints. It was very crude; in fact, soldering is one of the oldest known methods of making electrical joints and has not been improved on in any way except in the appliances used.

The new connector here pictured fills a long felt want and the connecting of wires is easily and quickly done. As will be seen from the illustration, it consists of a shell with this new instrument of hard rubber on which is mounted a thumb screw with a conical point, which fits into a cone-shaped head. The wires to be connected are twisted together and inserted in the hole at the left, then the screw is forced down by means of a pair of pliers or a screwdriver clamping the wires tightly. The resulting joint is perfect, both mechanically and electrically.

The advantage of this very clever connector will be appreciated when the number of accidents that it will eliminate are considered. With the old methods fire was often caused from the alcohol or gasoline used in the torch, damage was done by hot solder falling on furniture, etc., and the soldering acid splashing on various things.

How I Jumped from $1500 to $50,000 Yearly

"'Power of Will' Was My Guide"

"Three years ago I was making $1500 a year and working day and night. Today I make a thousand dollars a week and have time for other things as well. To the lessons in 'Power of Will' more than any other thing do I owe this sudden rise."

These are the exact words of an owner of "Power of Will." His name is not published for obvious reasons, but will be gladly given in confidence on request.

As remarkable as is his experience it might also be called typical of what this wonderful course in Will Training is doing for thousands of men and women in every walk of life who are using "Power of Will" as the stepping stone to greater accomplishment.

Partial Contents

The Law of Great Thinking.
The Four Factors on which it Depends.
How to develop analytical power.

How to acquire the skill of Creative Writing.
How to guard against errors in Thought.
How to drive from the mind all unwelcome thoughts.
How to follow any line of thought with keen, concentrated Power.
How to develop Reasoning power.
How to Handle the Mind in Creative Thinking.
The secret of Building Mind Power.
How the Will is made to act.
How to test your Will.
How a Strong Will is Master of Body.
What creates Human Power.

What Users Say

"I hand you $3 in payment; from what I have already seen I believe I can get $300 to $30,000 worth of good out of it."—C. D. Van Vechten, General Agent, No. 1 West Life Ins. Co., Cedar Rapids, Ia.

"'Will Power' is a compilation of mighty force. My first week's benefit in dollars is $900.00—cost $3.00; profit $897.00."—J. W. Heistand, 916 Tribune Bldg., Chicago, Ill.

"In my judgment 'Power of Will' is wonderful."—Owen J. McCaughey, Secy. of Corp. Securities Co., St. Louis, Mo.

"Enclosed find check; send 15 copies to our New York Office."—W. M. Taylor, Efficiency Expert the Overland Auto Co., Toledo.

"The character of 'Power of Will' is such that he who reads and puts forth effort will soon find himself out of the common herd."—F. A. Good, Pres. of Neb. Lumber Dealers' Assn., Cowles, Neb.

"I have carefully gone over 'Power of Will' and find it admirable."—Chas. Olin, Editorial Rooms, Boston Evening Transcript, Boston, Mass.

What is "Will Power"?

The Will is the motive power of the brain. Without a highly trained inflexible will, a man has about as much chance of obtaining success in life as a railway engine has of crossing the continent without steam. The biggest ideas have no value without Will Power to "put them over." Yet the Will, hitherto entirely neglected, can be trained into wonderful power like the brain or memory and by the very same method, by intelligent exercise and use.

If you held your arm in a sling for two years, it would become powerless to lift a feather, from lack of use. The same is true of the will—it becomes useless from lack of practice. Because we don't use our wills—because we continually bow to circumstance, we become unable to assert ourselves. What our wills need is practice.

"Power of Will"

by FRANK CHANNING HADDOCK, Ph. D., a scientist whose name ranks with such leaders of thought as James, Bergson and Royce, is the first thorough course in Will Power ever conceived. It is the result of over 20 years of research and study. Yet you will find every page in the 28 lessons written so simply that anyone can understand them and put the principles, methods and rules into practice at once with noticeable results right from the very start.

Meant for You

There are over 75,000 people in all walks of life who own "Power of Will." Among them are such master men as Judge Ben B. Lindsey; Supreme Court Justice Parker; Wu Ting Fang, ex-U. S. Chinese Ambassador; Lieut.-Gov. McKelvie of Nebraska; Assistant Postmaster-General Britt; General Manager Christeson of Wells-Fargo Express Company; E. St. Elmo Lewis, now Vice.-Pres. Art Metal Construction Company; Gov. Ferris of Michigan, and many others of equal prominence.

Never in the history of self-help literature has there been such a record. And the owners regard it as a veritable text book. It has been instrumental in changing the entire lives of thousands—making them dominant personalities, self-confident and eager, in place of the fearful, unhappy, unsuccessful men and women they formerly were. No matter what your position—whether an errand boy or the president of a mighty corporation—no matter what your age, from 17 to 70, Power of Will can change *your* whole life—can make a new man of you just as it has for so many others. Whatever you want in life is yours, be it money, power, prestige or happiness, if you but master the wonderful system of will training taught in "Power of Will."

Send No Money!

Although "Power of Will" is a 400-page leather bound book containing more material than many $25 correspondence courses, the price is only $3. The publishers will gladly send a copy free, for five days' inspection.

Send no money now. Merely mail the coupon on the right, enclosing your business card, or giving a reference. If you decide to keep the book, send the money. If not, mail the book back. Tear out and fill in the coupon now, before you turn the page.

THE PANDICULATOR

This University discovery is the most important health invention of the century. It remakes and rejuvenates the Human Body. It produces normal spines. It frees impinged and irritated nerves, corrects contracted muscles, shortened ligaments; eliminates congestion, improves circulation and drainage of the body. IT WILL INCREASE THE BODY'S LENGTH.

THE PANDICULATOR CO.
Cleveland, O.

MOON-POWER KEEPS

Eye Glasses Clean.

Of great benefit when eye-glasses steam or fog.

Imparts wonderful brilliancy to all lense surfaces.

A boon to camera users.

Price 25c., 50c. and $1.00 postpaid.

MOON-POWER MFG. CO.

Box 673 Plainfield, N. J.

SUCCEED IN LIFE

It's perfectly simple that you can't become a man of achievement and power and influence without

HEALTH—STRENGTH—VITALITY

Then why do you wait? Surely you don't expect to reach the choicest of earthly blessings over THE PILL ROUTE.

A pill pilgrim is one who thinks that he can swallow health and power in tabloid form. *He can't—you can't—it can't be done.*

THE STRONGFORT SYSTEM

is the answer. It is a scientific and authoritative application of scientific methods to Physical Culture. Its creator instructs *each pupil personally*. Do you want to read the life of the most powerful and symmetrical man ever known? Send for **INTELLIGENCE IN PHYSICAL AND HEALTH CULTURE**, enclosing 4c. in stamps for postage. Write now while they are still on hand.

LIONEL STRONGFORT
PHYSICAL CULTURE EXPERT
Dept. C 46 Havana, Cuba

DON'T BE BASHFUL

Are you timid or self-conscious? Do you blush, lose your nerve and become confused easily? Are you bashful and unsuccessful in love, social or business affairs? My illustrated **FREE TREATISE** tells how these faults may be promptly and permanently overcome. Address: **M. DeBETTS, Station 55, JACKSON, MICHIGAN**

BOOST
THE ELECTRICAL EXPERIMENTER
to your friends. It will make the magazine better.

DO YOU

own a wireless station, either for sending or receiving? If you do, don't fail to join the greatest Wireless Association in the country: THE RADIO LEAGUE OF AMERICA. If you believe in the preparedness of your country, if you wish to help Uncle Sam, if you wish to have your station officially recognized, join the LEAGUE, a national, non-money-making organization. Beautiful engraved and sealed certificate, FREE to all members. NO DUES OR FEES WHATSOEVER.

Honorary Members: W. H. G. BULLARD, U. S. N.; PROF. REGINALD A. FESSENDEN; DR. LEE DE FOREST; DR. NICOLA TESLA.

Send stamp for large 8-page information booklet. **DO IT NOW.**

BRAUN-TUBE FOR RESEARCH WORK ON ELECTRIC OSCILLATING CURRENTS

(*Continued from page 695.*)

ber of turns, placed far from the tube so that it has no influence on the ray. If we introduce into the coil 3 iron wires, the deflection of the ray diminishes, for we have increased the impedance of the circuit.

Add to the coil 3 a condenser C, as shown in Fig. 14, for the usual technical alternating current. We observe a certain deflection. With suitable chosen dimensions of the coil 3 and the condenser it is now possible to increase the deflection by introducing iron wires into the coil 3.

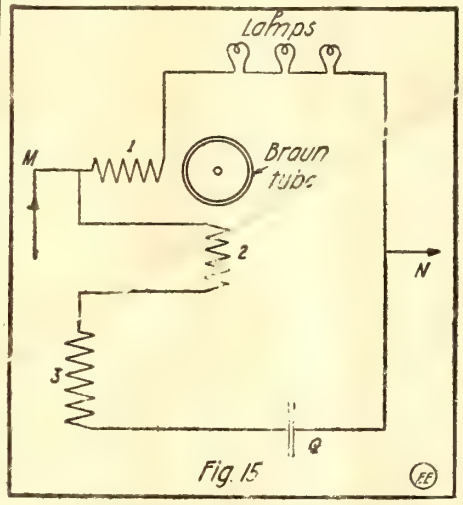

Fig. 15. Interesting Experiment with Divided Circuit and Braun-Tube.

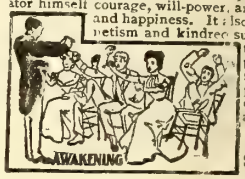
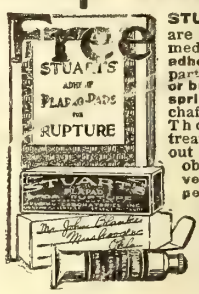
Still another interesting experiment wherein the Braun tube plays an important part is the demonstration of a divided oscillating circuit having on one branch a reactance composed of a capacity Q and inductance L-3 in series, while the other branch contains a resistance; i. e., incandescent electric lamps P, as depicted in Fig. 15. The branch MPN is in phase with the electro-motive force; i. e., the difference of potential between M and N. The branch MQN has a phase difference; for that reason we observe on the screen of the tube an ellipse. Now let us introduce into the coil 3 an iron wire, and in so doing the shape of the ellipse is changed. As more iron is added to the coil the ellipse finally takes the shape of a straight line. If the core is removed the ellipse resumes its original form.



[*It is generally known that the Braun tube is the only apparatus available that will record correctly vibrations above the audibility range. In fact, frequencies up to several millions were actually recorded without any trouble whatsoever. This simple device supersedes the ordinary oscillograph for recording electrical vibrations. Moreover, the oscillograph is a thousand times more complicated and expensive; and furthermore, cannot start to do the work accomplished by the Braun cathode tube.—Editorial note.*]

HYPNOTISM!

Be a HYPNOTIST and MAKE FUN and MONEY



It takes but a few hours to learn. The study is both easy and fascinating. Hypnotism is an endless source of fun and wonder. If you know how to Hypnotize you can perform some of the most marvelous feats imaginable. You can do a hundred amazing things that other people cannot do. You can surprise your friends and make yourself popular. You can place others under the strange and mystic spell. You can compel them to think, act and feel just as you wish. If you want to make money you can do so by giving entertainments, treating diseases or teaching the art to others. Why work for others, when you may master this money-making profession so easily? Investigate NOW! You may learn at your own home. I will send you my free treatise for the asking. It tells you about Hypnotism and how you may easily learn it. It is profusely illustrated and is written in a simple style easily understood by all. Anybody may learn from it of how the Hypnotic Spell sways the will of its subjects, heals, reforms the degraded, overcomes bashfulness, helps position, amuses an audience for profit, and gains for ator himself courage, will-power, and a means to health and happiness. It also treats fully on Personetism and kindred subjects. Remember, this tise is absolutely free. Simply write for it, and it sent by next mail, all charges paid. Don't send any money or stamp, but send your name and address today. Address

Stop Using a Truss

STUART'S PLAPAO-PADS are different from the truss, being medicine applicators made self adhesive purposely to hold the parts securely in place. No straps or buckles attached—no obnoxious springs. Cannot slip, so cannot chafe or press against the bone. Thousands have successfully treated themselves at home without hindrance from work—many obstinate cases cured. Soft as velvet—easy to apply—inexpensive. Awarded Gold Medal. Process of recovery is natural, so afterwards no further use for trusses. We prove it by sending you Trial of Plapao absolutely free. Write today.

PLAPAO CO., Block 221 St. Louis, M

Super-Conscious DEEP BREATHING

Over 50,000 Satisfied Patrons

of my special method of "Super-Conscious DEEP BREATHING" warrants my claim that it is the only scientifically correct method of re-vitalizing the blood, building nerve force and constitutional strength, thereby enabling anyone, with a few minutes' practice, to throw off fatigue, depression and brain fag. Send for my FREE book on "DEEP BREATHING." Paul Von Boeckmann, Respirator and Nerve Specialist, 2800 Tower Bldg., 110 West 40th St., New York.

GET ON THE VAUDEVILLE STAGE

I tell you how! Fascinating profession either sex. Big salaries. Experience necessary. Splendid engagements all waiting. Opportunity for travel. Theatrical agents and authorities endorse methods. Thirty years' experience manager and performer. Illustrated book **"All About Vaudeville"** sent **Free** Frederic La Delle, Sta. 177 Jackson, M

THE BOYS' OWN LABORATORY
CHEMCRAFT

A Complete Outfit of
CHEMICALS - (39 Chemical Reagents
APPARATUS - (All Necessary Apparatus
INSTRUCTIONS (The Chemcraft Book

for performing over 50 Different Experiments. Each experiment can be repeated many times.

Under the heading "Chemistry and Its Application to the Industries" are many experiments which the products of our great chemical industries are really manufactured on a small scale. Everything is explained in a clear interesting way.

Chemcraft also contains 30 mysterious experiments in Chemical Magic. It's great fun to astonish these to your friends.

If your dealer does not have Chemcraft we will send yours direct. Price $2.00 postpaid. Descriptive literature sent on request.
